
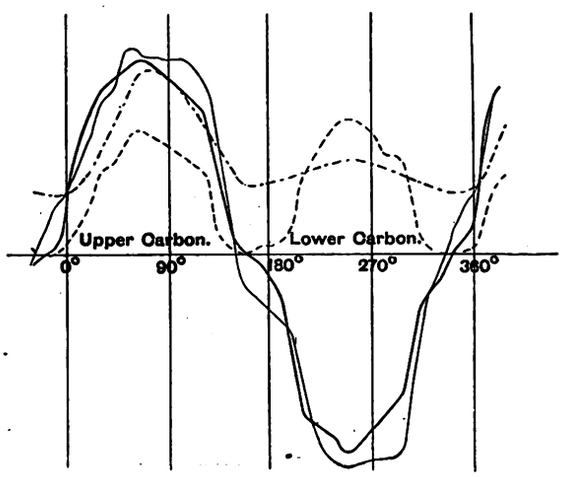

Fig. 4.

is expressed by an increase of temperature and light. This is especially seen in the flat curve (Fig. 3), but not in the pointed curve, as the current falls too rapidly. As regards the displacement

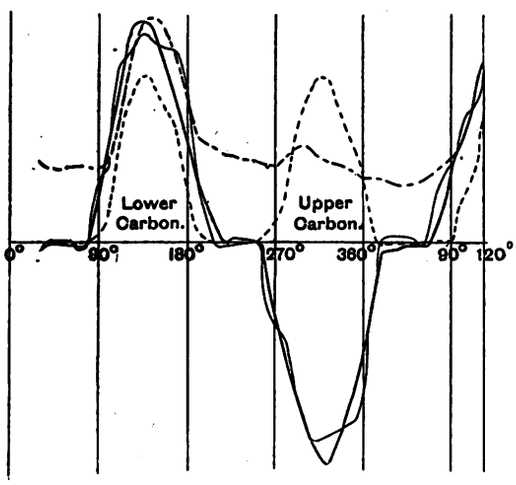

Fig. 5.

of phase between volts and current, it is decidedly positive near the zero line, *i.e.*, like that produced by self-induction. It is also seen that when the current has a high value the current suffers a negative displacement. The curves of current and light in Fig. 3 are decidedly pushed to the left with reference to the pressure. This is easily explained on the assumption of a thermo-electric counter E.M.F. in the arc. We assume that at each carbon point there is a thermo-electric force between the carbon and the atmosphere directed towards the carbon. Since the two minima are approximately equal, the thermo-electric forces must also be approximately equal, and must neutralise each other. Hence the slight self-inductance in the mechanism of the lamp and in the carbons is brought into play, and displaces the current curve towards the right. At times of large current there is a great difference of temperature between the carbon points; the thermo-electric force at the positive carbon is in excess, and produces a counter E.M.F., which reduces the current. Owing to the accumulation of heat the temperature on the right-hand side of the crest of the current must be highest, and must reduce the current more on this than on the left side. Hence the crest looks as if pressed towards the left. A similar effect may be noticed in the other curves.

REMARKS ON STEAM PIPES.*

BY J. T. MILTON.

With regard to material, by far the greater number of steam pipes have been and are being made of copper, but of late wrought iron has in a few cases been used.†

Steam pipes have to withstand considerable changes of temperature, and their length is consequently liable to continual alterations. Their attachment to the engine may be liable to slight alteration in position, owing to the working or vibration of the engines or vessel; while those to the boilers are also liable to small displacements, due to the contraction or expansion of the boilers from variations of temperatures. All these changes are generally taken up or provided for by the deformation of easy bends in the pipes, or by expansion stuffing boxes where the pipes are straight.

It must be remembered that the advance of engineering of late has not only increased the steam pressures used—and, therefore, the temperatures also—but engines are, in general, of much greater size and power than those used years ago. The steam pipes now, therefore, are, as a rule, larger in diameter, much thicker, and are subject to greater changes of temperature and expansion, &c., than formerly. These all make the pipes so much stiffer, or more rigid, that with many pipes, even when made of copper, their rigidity is so great that their yielding or altering form cannot be relied upon to relieve expansion strains, which have, therefore, to be provided for in the same way as they would need to be if the pipes were made of cast iron. Concurrently with the trouble of providing for expansion, &c., with thick and large pipes, there arises also a difficulty in manufacturing them. The usual method of making pipes of large diameter is to make them, both bends and straights, from copper sheets, the straights, except in very large pipes, having one seam along the entire length, the bends having two seams along the sides, the saddle and back pieces being each worked up from one sheet. The seams are invariably brazed, the edges of the copper being thinned down to form a scarph. Now, the difficulty of satisfactorily brazing a joint of this description increases rapidly with the thickness. The heat has necessarily to be applied from the outside, and has to pass through the thickness of the metal to reach the brazing solder, and thus the risk of overheating the copper on the outside, and consequently burning it, is much greater with thick than with fairly thin copper. There is also a further danger of deoxidising the copper, both in the brazing and also in the previous annealings to which the copper has to be subjected. To this further reference will presently be made. All these considerations have made some of our prominent engineers look with disfavour upon copper as a material for large steam pipes, and to turn their attention to iron or steel. Endeavours have been made to introduce seamless pipes of large size for these purposes to avoid the risk of brazing. These are made by several firms, and lately, I believe, with a certain amount of success; but amongst some of the earliest of those made some serious longitudinal defects, probably arising from a local defect in the original ingot being drawn out lengthwise in the manufacture of the pipe, caused them to be looked upon with a certain amount of suspicion, besides which the great difficulty of making satisfactory bends with these large pipes has, no doubt, had some influence in preventing their more general use.

The method of manufacturing the Elmore copper pipes has been publicly described, and it has been claimed that it renders the probability of their containing any latent defect very remote. The following results of tests made by the Elmore Copper Company upon two tubes made by themselves, and on one seamless tube and

				10·00	On mean section.

NOTE.—All the brazed pipes burst by tearing at the edge of the brazing.

It will be observed that the seamless drawn, and also the Elmore tubes, showed a high degree of strength, which indicated that they were *hard*, or *unannealed*, a condition in which they would not be used in practice, as steam pipes are always left annealed, or very slightly hardened, by planishing. To show the actual strengths of the copper in an annealed condition, 28 test pieces were cut from these pipes, and tested in an ordinary tensile testing machine, some of them being annealed, others unannealed. The results of these tests are given in Table II. :—

From these tensile tests it will appear that Elmore copper even when hard has much extension, but that it commences to elongate at much less stress than annealed ordinary copper; while, when annealed, its behaviour as to ultimate strength and extension is very similar to that of good commercial copper, but it appears to commence to elongate at somewhat lower stresses than the latter.

While treating of copper pipes it may be well to say a few words as to the qualities of copper. Engineers generally purchase their copper sheets or tubes without subjecting them to rigid tests, relying upon the reputation of the makers for supplying a good article, and not troubling about the chemical composition, &c., so long as it is found to work well. In view of the great ductility of copper, the working of even an indifferent sample of copper may not be sufficient to detect its quality, especially when made into straight pipes. Commercial copper is practically never pure, the amount of different impurities found in it being probably greater than in the case of any other metal commonly used. Information on this question can be found in the *Transactions* of Mechanical Engineers, No. 2. 1893, where two Papers will be found on the subject, by Prof. W. C. Roberts-Austen and Mr. W. Dean respectively. An opinion is generally held by locomotive engineers, coppersmiths, and many others, that the commercial copper of the present day, although chemically purer than that of years ago, is inferior in respect to its lasting qualities, both as regards ability to resist corrosive influences and also to withstand fatigue without cracking. Accordingly, for some purposes, what may be termed impurities are added to the copper for the purpose of improving some of its properties. The Papers referred to and the discussion on them appear to show that arsenic up to a proportion of ½ per cent. is certainly not injurious, and is probably beneficial, improving both the tensile strength and ductility of the copper. On the other hand, bismuth is objectionable, even small quantities, such as 0·1 per cent., being sufficient to make the metal absolutely unreliable when heated above the boiling point of water. The following figures, extracted from the Paper by Prof. Roberts-Austen, show these points. Particulars are given in the following table for comparison of pure copper and of copper containing arsenic or bismuth, in all cases the copper being as cast, not hammered :—

—	Temperature of copper.	Tensile strength per sq. in.	Percentage of elongation.
	Deg. Fahr.	Lbs.	
Pure copper ...	64	18,450	20
	64	19,740	35
Copper containing 1·2 per cent. of arsenic.	68	24,840	20
	266	20,470	16·6
	435	16,460	15
	511	14,340	4
	655	14,860	10
Copper containing 1·5 per cent. of arsenic.	59	26,460	20
	64	25,400	25 to 50
	241	23,460	26
	419	19,460	37
	500	18,360	Irregular.
	586	15,030	0
			Percentage of elongation in 4in.
Copper containing 0·1 per cent. of bismuth.	59	18,020	20
	214	11,510	15
	324	5,620	0
	390	3,860	0
	525	4,940	0
	558	2,770	0

A small quantity of lead, say under 0·1 per cent., does not appear to be objectionable, but large quantities are not desirable. On the other hand, it appears that nickel and silver are not detrimental, the samples quoted by Mr. Dean as containing the largest proportions of these elements having given satisfactory results in use. It has been stated that the tensile strength and ductility of copper vary according to its composition, but with the same mixture of metal they vary very much more with the mechanical treatment it undergoes. If properly annealed its tensile strength is compara-

Digitized by Google

tively low, and its ductility is high. In comparing the qualities of copper, therefore, it is necessary to fix the standard as being thoroughly annealed. To show the effect of annealing and of work, the following tests recently made may be quoted. A copper tube was drawn in one operation from 3 W.G. to 11 W.G. (a very excessive draw, more than doubling its length). Its tensile strength when drawn was 24·38 tons per square inch, but its elongation was only 3·1 per cent. in 4in. After annealing (or possibly only partial annealing) its tensile strength was 18·66 tons per square inch, and its elongation was 44 per cent. in 4in. A good average result with annealed copper is 14 tons per square inch, and 40 to 45 per cent. elongation in 4in.

While treating on annealing it is interesting to compare the difference in the methods adopted in tube works and in ordinary coppersmiths' shops. In the former the tubes are annealed after every draw. They are raised to a temperature of from 800°C. to 900°C., say from 1,500°F. to 1,650°F., and are kept at that temperature for some little time, after which they are quenched in water. The tubes are uniformly heated over their whole length, care being taken that the flame is clear and contains an excess of oxygen. In the coppersmiths' shop both sheets and pipes are heated over open coke fires; the flame may possibly be reducing—that is, may have a deficiency of oxygen—if the fire is a thick one. The sheet or pipe is moved about over the fire, spot after spot being heated, generally to a dull red, and after the whole surface has been thus treated the copper is either quenched or allowed to cool, and is considered to be annealed. It thus depends upon the workman's care and judgment to ensure that every part has been heated, and there is considerable probability that some small part may escape full heating. Further, the heating cannot be uniform, nor can any part in general be retained at the red heat for any considerable time, nor is the temperature at any part raised to the same degree as is usual in tube works. The influence of time upon annealing has, so far as I know, not been much experimented upon, neither has that of the various impurities; but I am informed by Dr. Watson that annealing may be efficiently carried out at lower temperatures than 800°C., but that it requires longer time at the lower temperatures than at the higher.

To show the influence of temperature upon annealing, the following experiments are deserving of notice. A sample of copper was found to be abnormal in its behaviour, being brittle instead of ductile. Its composition was as follows:—

Copper	99·693
Nickel	0·260
Iron	0·027
Arsenic	Trace
Silver	0·020
	100·000

Six test pieces were cut off it, one was tested unannealed, and five were annealed at different temperatures. The following were the results:—

Temperature at which annealing was performed.	Tensile strength, tons, per sq. in.	Extension per cent. in 4in.	Fracture.
Unannealed	14·9	0·0	Granular.
Faintly visible red, about 525°C.	12·13	6·2	"
Dull red, about 700°C.	11·78	3·1	"
Cherry red, about 850°C.	13·89	4·7	"
Bright red, about 900°C.	14·2	14·0	Silky.
Approaching yellow, 1,000°C.	15·64	25·0	"

I am not able to say what caused the abnormal brittleness in this case, but after annealing at the high temperature the material regained a fair amount of ductility; and, after subsequent drawing or cold rolling, behaved in a perfectly normal manner. Annealing, however, at red heats left the material brittle. In this case very little time was allowed for annealing, the test pieces having been heated in an open fire and then quenched, the influence of time on annealing not having been so fully appreciated as it should have been.

Turning our attention to other materials suitable for steam pipes, we find, practically, only three, viz., cast iron, wrought iron, and mild steel. Cast iron has the advantage that it can be made in any shape, straight or bent, and that tees or junctions can be made of it. On the other hand, if the pipes are of the same strength as wrought iron or steel, they are much heavier. Wrought iron and steel may both be made with a lap-welded joint, but, whereas welds in iron are apparently looked upon as trustworthy after a severe hydraulic test, those in steel do not appear to have the same confidence reposed in them, as they generally have a riveted butt strap fitted over them. Apparently, therefore, iron pipes are preferable to steel, unless the latter are made seamless. With pipes of either iron or steel, manufacturing conditions appear to require them to be of such a thickness that either has a very large margin of strength compared with the pressures now being used, or even with those higher pressures to which marine engineering appears to be tending, so that there is no advantage in this respect in using steel rather than iron.

The question of flanges for iron pipes is important. Most of those hitherto used have had forged iron flanges screwed on, riveted over on the face of the flange, but flanges are now being electrically welded to the pipes in some cases, and welded by machine hammers in others, these plans apparently giving sound results without the chance of leakage, which screwed flanges might develop.

Regarding provision for expansion of pipes, whether of copper, iron, or steel, a point sometimes lost sight of is that it is not sufficient to provide a faucet joint in a straight length of pipe, but provision must also be made to anchor the ends of the length of pipe for the expansion of which provision has to be made, and so compel the movement of expansion to take place in the part provided for it, otherwise the end pressure on the pipes, amounting to several tons in all but the smallest pipes, will cause the joint to slide in the wrong direction. This has occasionally been overlooked in pipe designs. It is always difficult to provide for the expansion of large bends without producing excessive strains, so that, as far as possible, pipes should be made straight.

The only other point to which reference will be drawn is that of providing means of draining steam pipes. More than one fatal accident has been thought to be due to the presence of water in the pipes. In cases where it is the practice to always raise steam in all the boilers simultaneously, the stop valves on the boilers, if opened before steam is raised, may be the best possible drains for the pipes; but where there is more than one boiler it may often happen that, even if all the boilers are invariably used for steaming purposes, one only may be used in port for auxiliary purposes, and in this case leakage from its main stop valve will find the steam pipes leading to the other boilers receptacles for the condensed steam, which, if not drained, may be dangerous when opening the stop valves when raising steam in the other boilers. It is noteworthy that more than one of the serious accidents with pipes has occurred at the moment when stop valves were being opened. Too much attention cannot be paid to the provision for draining steam pipes, and it is considered that it is preferable that these should be automatic, or such as not to require personal attention.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November 30, 1895.*

The Standard Telephone Company.—An enterprise heralded some months ago in the manner of earlier electrical promotion days seems coming to a crisis. We refer to the Standard Telephone Company, which last April announced with a great flourish its entry into the field as a rival of the Bell monopoly. A capitalisation of no less than $160,000,000 was claimed, and a list published of its supporters, which comprised some of the most prominent names in the United States. Mysterious allusions were made to wondrous telephonic patents which in due time would be disclosed, and a telephonic service at a merely nominal price was promised. Thus far, however, the Company has made no installations and has given no evidence whatever of the possession of any telephone patents beyond claiming to control some old ones well known in telephone circles, and which have never been supposed to possess any practical value. At present the Company is being vigorously attacked, the charge being made that it was merely formed to obtain money from the numerous branch companies which were organised through false representation as to non-infringing apparatus, by means of which it was asserted successful competition with the Bell Company could be undertaken. No satisfactory answer has been made to these charges, and the very respectable gentlemen whose names have been the sole stock-in-trade of the Company are beginning to recognise that they may have been used as decoys in a rather disreputable scheme.

"Motocycle" Contest.—A contest of motocycles, for four prizes offered by a Chicago newspaper, ranging in value from $2,000 to $500, was announced several months ago, the time for the trial being set for the commencement of the present month. Sixty-three entries were made, and it was confidently asserted that 25 vehicles at least would participate in the race. After various postponements the contest came off on Novem-

Digitized by Google

ber 26th, at Chicago, but with only six motocycles in the race. The length of the course was 54 miles in all, and on the day of the trial the ground was covered with slush and snow, the latter being 12in. deep in some places. Two of the six starters were electrical carriages, one of which ran only 12 miles, and the other 16. Only two motocycles, both American gasoline vehicles, covered the entire distance—one in 10 hours and 23min. and the other in one hour and 35min. additional time. A French motocycle, from the manufacturer of the vehicle which recently won the Paris-Bordeaux prize, broke down after covering about half the course.

CORRESPONDENCE.

THE COST OF LIGHTING BY GAS AND BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As a subscriber to *The Electrician*, I have for the first time in your issue of this week seen a report by Mr. Trotter on the cost of gas and electricity at Hastings, and I would ask by your courtesy to be allowed to make a few remarks thereon.

All engineers who are engaged in the lighting industries, whether gas or electrical, must recognise that there are two sides to every question, and nothing is gained in the long run by erroneous statements made to damage one another. Having had an extended experience in both systems of lighting I have recognised the superior advantages and convenience of electric light for certain purposes, and we have ourselves put down a complete installation on our gas works for special uses, and so are fully acquainted with the possibilities of electricity for lighting purposes. I am also conversant with the admirable work done by Mr. Trotter in the measurement of outdoor illumination; but that is a very different thing to the photometrical examinations of the real value of different descriptions of light, and as a photometrist I should take serious objection to many of the arrangements made for the tests described in this report as not being conducive to that strict accuracy without which the results recorded have little real value, and this, I think, Mr. Trotter practically admits, but seeks to confirm his tests by certain tests made by others and used for the purposes of showing exaggerated comparisons. How inefficient some gas burners are under certain conditions has nothing to do with the real lighting value of the gas.

As regards the results given for the electric lamps, they are certainly taken to their very best advantage, whilst the gas burners are taken at their very worst, and show how gas can be wasted, which is equally possible with electricity. In either case the results are not obtained in actual practice. The statement that the burners tested are similar to those usually in use in the town is incorrect. The "Christiania" burner is an admirable one, but unfortunately its price is rather high, which makes its use somewhat prohibitory to all but a few; whilst the cheap burners (costing about ½d. each) are comparatively little used now, and not in the manner described. It is very certain that the "Christiania" burner used by Mr. Trotter must have been defective in some way, as it is provided with a governor which makes burners of this description unaffected by pressure, as that remains constant at the point of ignition under pressures varying from 10 tenths to 40 tenths. It is also a well-recorded fact by different experts that this burner with 16-candle gas develops a lighting value of quite 8 candles per cubic ft. of gas consumed. The question of globes should not be taken into consideration, as the same results will follow the use of obscured or unsuitable ones whichever source of light is used.

The real question is: What is the initial value of the light in each case for a certain consumption, irrespective of how badly people may misuse it or waste it?

The Parliamentary standard for gas in Hastings is 15 candles by the standard burner consuming 5 cubic ft. per hour, which has to be tested on a photometer with all the standards and accessories stipulated by the gas referees appointed by the Board of Trade. In order to comply with the Act the gas is sent out nearer 16 candles than 15, in order to be on the safe side. On October 11th, when Mr. Trotter made his tests, the recorded illuminating power of the gas going into the town was 15·93 candles. The generality of people here use governor burners of some description (costing about 1s. each), speaking only of the ordinary way of using gas, and these will easily and do develop a lighting value of quite 8 candles per cubic ft. of gas consumed. Mr. Trotter evidently does not quite appreciate the conditions which are necessary for gas distribution over large areas as regards "pressure," especially in a district like Hastings and St. Leonards. Suffice it to say that all pressure beyond that necessary to give to fulfil statutory requirements, is to the great disadvantage of the gas suppliers more than the consumers, as they can simply and easily control it, whilst extra pressure in the mains means loss by leakage.

In conclusion, the broad fact remains that in actual practice a good ordinary gas burner consuming (say) 5 cubic ft. per hour of 16-candle gas, and an ordinary 16-candle power (56 watts) electric glow lamp, both used under similar conditions, have the same useful lighting effect, and their relative cost can be easily calculated without any elaborate formulæ. Assuredly no one acquainted with the possibilities of both gas and electricity would be deceived by the "assumptions" in Mr. Trotter's report.—Yours, &c.,

CHAS. E. BOTLEY, Assoc.M.Inst.C.E., &c., &c.,
Engineer, Hastings and St. Leonards Gas Company.

Hastings, December 9, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In an article in your issue of December 6, 1895, in which you evidently refer to a recent correspondence in the local Press between the engineer of the local Electric Light Company and myself, you reproduce two of his statements—viz., that "a local critic was persuading the Hastings public that electric lighting cost three times as much as gas lighting," and that "the Hastings gasophiles have good reason to regret that they ever made exaggerated charges against glow-lamp lighting," both of which statements I have already refuted.

My statement was "that gas at 3s. a 1,000 is as cheap again as electricity at 6d. per unit," and this I substantiated, *not* by adducing the words of those interested in gas, but by the testimony and experiments of electricians themselves, taken from their own works or from the *Electrical Review*. To my mind there is a difference, which your informant cannot see, between twice and three times; whilst to talk of electric lighting as costing three, or any other number of times as much as gas lighting, without stating the actual cost of each, appears to me nonsense.

The second statement is one easily and, it is doubtless considered, safely made, because it is difficult to meet. I can only say that the alleged exaggerations by gasophiles are pure assumption, and my local opponent has *not* produced or named one single person connected with the Gas Company to support his statement, simply because the assumption is baseless; and, if fact is as valuable as assumption, it is a fact that £20 shares in the local Gas Company have, since this alleged occasion for regret, sold for £48. 5s., the highest amount they have ever fetched, whilst shares in the Electric Light Company failed to obtain a purchaser.—Yours, &c.,

December 12, 1895. GEO. G. GRAY.

LEGAL INTELLIGENCE.

Sandon and others v. the Chelsea Electricity Supply Company (Limited).

This case again came on for hearing before Mr. Justice North in the Chancery Division on Friday last, on a motion for a sequestration order against the defendants for non-compliance with an order of the Court made on June 21st last, but the operation of which was suspended until October 31st.

Mr. Warmington, Q.C., and Mr. Badcock appeared for the plaintiffs, Robert Frederic Sandon, the landlord of certain flats in Cadogan-gardens, and two of his tenants; and Mr. Fletcher Moulton, Q.C., Mr. Vernon Smith, Q.C., and Lord Robert Cecil for the defendants.

Mr. WARMINGTON said that on May 24th an order was made that the writ should be treated as the statement of claim, and that the defendants should put in a statement of defence within 14 days. Leave was also given to the plaintiffs to expedite the trial of the action. After the defence had been delivered the plaintiffs moved to expedite the trial. The defendants then said they would treat this motion to expedite as the trial of the action, and submitted to the injunction of June 21st. The order was to the effect that the defendants, their servants or workmen, should be perpetually restrained on and after October 31, 1895, from so working their engines and so carrying on their works in Cadogan-gardens, Chelsea, as to cause a noise, vibration, or otherwise to interfere with the enjoyment of the occupants of residential flats at 21, Cadogan-gardens. Mr. Warmington said that since October 31st the plaintiffs still suffered from this nuisance of vibration and noise, and therefore they had come to the Court for a sequestration order against the defendants for not complying with his Lordship's order.

In reply to his Lordship, Mr. MOULTON said he did not suggest that his clients had a statutory right to create a nuisance. He should argue that his clients had reduced the interference with the plaintiffs' property to such a pitch that it was no longer a substantial interference with the enjoyment of the property, and was no longer a nuisance. He should rely on two points: first that there was no nuisance, and secondly that his clients had done all they could, and all that it was reasonable to expect them to do, during the period that had been allowed to remove all interference, and they had succeeded to a very great extent.

Mr. Justice NORTH: Your first point is no nuisance; your second point is that, although you have not completely removed the nuisance, you have done your best and done all you could in the time, and if you have a little more time you will get rid of all nuisance?

Mr. MOULTON: Yes, my Lord. We have spent £10,000 in changing the type of machines and in altering our building.

Mr. WARMINGTON then read a number of affidavits from the plaintiffs, several residents in the flats, and visitors to the residents. All testified to the great vibration created by the defendants' machinery, causing water bottles, lamps, glasses, ferns, &c., to shake and rattle. One affidavit stated that the noise was like that experienced when next to the engine room on board a large steamship; another that the noise was like that of a screw of a steamship whilst in motion; another compared the noise to an earthquake; and other witnesses said their health had suffered by the noise, and that they could not read or write.

Mr. VERNON SMITH said that the electrical energy was now generated three-quarters of a mile away from the station in Cadogan-gardens.

Mr. MOULTON said that, shortly, what had been done was this:—The engine room had been cut in two. The portion next to the plaintiffs' premises had been made a separate room, and a brick wall had been erected right across the engine room. In this separate room were placed three transformers but no engines. These transformers could not possibly cause any vibration. They were worked from energy supplied by a distant engine with transformers. With regard to the other portions the defendants had reduced the number of large engines to two instead of three, and the number of small engines to four instead of eight. They had tried to do more than that; they had tried to obtain a class of engines which were less liable to cause vibration, and they had done their best to get them, but they had not yet been delivered.

Affidavits in support of the defendants' case were also read from General Webber, Deputy Chairman of the Company, Sir Frederick Bramwell, Prof. Perry and others.

Mr. MOULTON said that to prove how absolutely dominant the imagination of some people might be, he would mention that, on the occasion when one witness said the vibration was so great that the fireirons rattled, there were no engines working at all.

His LORDSHIP said that after hearing the evidence his impression was that the defendants should have longer time to complete the alterations which he was satisfied had to some extent been made. If the Court were now considering finally whether a sequestration order should be made or not, he would have to do what had been done in another case—namely, to employ an expert to go and see the premises and report to him. One case in which there was a question of nuisance, and in which there were strong affidavits on both sides by witnesses who were quite honest, he was pressed to go and see the place himself. He did not care to go when everything was put nice and clean, but he went himself one night without telling anybody, and he found that two or three witnesses on one side had described what he found to be the case with wonderful accuracy. His Lordship said that although his impression upon the evidence was that the defendants should have more time, his mind was quite open to conviction one way or the other.

Mr. MOULTON said the defendants were going to make very large further changes, and, after consulting his clients, he proposed that they should continue with all diligence to make these changes, he undertaking on their behalf that no machines should work after eleven at night; after that hour only the batteries and the transformers should work, and, as far as the defendants could, they would remove all the vibration before eleven. That would, at all events, preclude any possibility of any disturbance or any vibration late at night. In doing this he (Mr. Moulton) must not be taken as making any admission against his clients. The delay was only wanted for the purpose of carrying out the order in obedience to his Lordship. Mr. Moulton also said he was perfectly willing that his Lordship should name some expert to examine the premises.

Mr. SWINFEN EADY (for the Rev. M. Fowler, another complainant), Mr. WARMINGTON and Mr. BADCOCK then addressed his Lordship, the last-named gentleman arguing that it was not a question of diminution of the nuisance, but a question of nuisance or not. If there was still a nuisance the plaintiffs should succeed, and the defendants were not entitled to any further indulgence.

After some further discussion his Lordship, in giving judgment, said that he had come to the conclusion upon the evidence in the case that he ought to give further time to the defendants. He did not think that the nuisance, which the judgment showed did exist at the time it was pronounced, had been entirely removed. The defendants had done a great deal of work which had cost them much money. Of course, if the works could not be carried on without a nuisance to the plaintiffs, the defendants would have to close them altogether, no matter what inconvenience or pecuniary loss resulted to them from it. He was satisfied that they had not spent this large sum of money without some expectation that they would be able to leave the works where they were. Then there were certain other facts which had influenced him in the view which he took. It was clear that the engine power of the defendants had been reduced by one-half, and he could not believe that there was the same noise or vibration from engines with half the power that there was when there was double the power. No explanation had been offered about that. He was satisfied that there had been a *bonâ fide* attempt on the part of the defendants to comply with the order of the Court. Getting new machinery in must necessarily take some time, and delay must be caused by it. The judgment that was given and consented to by the plaintiffs showed that some time was necessary for the defendants to make the necessary alterations and improvements, and looking at what the defendants had done, he was inclined to say that the time had not been enough, and he would therefore grant them three months' longer time from that day in which to complete the alterations. The only question remaining was as to what terms he must impose on the defendants. He would require, and would accept, the undertaking of Mr. Moulton that the defendants would not work any steam engine after 11 p.m., and would complete their alterations then in progress as early as possible.

Some question was then raised as to whether the plaintiffs would wish an expert to inspect the defendants' premises periodically, to see if the alterations were being carried out satisfactorily.

Mr. WARMINGTON stated that the parties between them could probably agree on some gentleman to do so, but if not an application would have to be made to the Court.

Boyes v. Wellington and Co.

In the City of London Court, before Mr. Commissioner Kerr, was heard an action brought by Mr. Stephen Boyes, of Margate, to recover the return of £6. 10s. from the defendants, Messrs. Wellington and Co., electrical engineers, 73A, Queen Victoria-street, E.C., the price of one of their National Combination Chucks, with reversible jaw. The plaintiff had purchased the chuck of the defendants, they guaranteeing that it would work perfectly, to use in connection with certain electrical machinery. The defendants assured the plaintiff that the chuck was "dead true," and gave the plaintiff a printed description, in which the special virtues of this particular device were enumerated. When he took the chuck home he put it in a lathe, and, he alleged, found it was not true, and was therefore useless. The work produced by it was defective and of a useless character, and he therefore asked to have returned to him the £6 he had paid and 10s. by way of damages. It was tried in a new lathe.

For the defendants it was said that they made similar chucks by the thousand, and had never before had a similar complaint. It was simply impossible for the chuck to be untrue. The plaintiff did not return the chuck for three months and a-half, and they then, not unnaturally, refused to take it back.

Mr. Commissioner KERR said the proper course was to have the chuck honestly tested by an engineer, the cost to fall upon the person who was in the wrong. He was surprised at any difficulty being made about such a matter by a man who carried on business in the City of London, except that morality in trade was not what it should be.

The case was then referred to an expert, he to report to the Court.

Mitchell and Co. v. Nicholls.

In the Westminster County Court on Tuesday an action was brought by the plaintiffs, a firm of electrical engineers, to recover a balance of account of five guineas in respect of electric lighting work done.

Mr. DAVID MITCHELL said that in November of last year he had a conversation with the defendant, who was desirous of having the electric light fitted up at his house at Hampstead. Witness offered to give a price for the work, but the defendant said it did not matter, as he wanted it got on with without delay. Acting upon those instructions he (plaintiff) carried out the order in accordance with the defendant's wishes, and in due course an account for £15. 5s. 4d. was rendered, and various sums were paid on account from time to time; but when the balance was pressed for the defendant set up the contention that he was not liable on the ground

Digitized by Google

that there was a verbal contract to do the work for a fixed sum of £9. There was no truth in that suggestion, however, and the present action was to recover the balance due.

The DEFENDANT appeared in person, and swore most positively that the plaintiff told him the cost of the work should not exceed £9, and it was upon that understanding that the order was given.

His HONOUR said that if such a bargain was ever made it was strange that it was not put into writing.

The jury found for the plaintiffs, with costs.

Judgment was entered accordingly, and his Honour refused the defendant's application for time in which to pay.

POLICE INTELLIGENCE.

Alleged Fraudulent Marking.

At Clerkenwell Police Court on Wednesday Alfred Attride, of Richmond-road, Kingsland; Edward Ingold, electrical engineer, of Woodlands-road, Leytonstone; and George Cosgrave, electrician, of Church-street, Putney, were charged on a warrant with unlawfully applying to certain lamp-holders marks which resemble the trademark of the Edison and Swan United Electric Light Company (Limited).

Mr. WONTNER, who represented the Company, said the defendants would be charged with conspiring to defraud the Edison and Swan Company, who carry on business as manufacturing electricians and electric supplies dealers at Queen-street, London, E.C., and also with infringing the Merchandise Marks Act. Ingold was formerly in the employment of the Company as a clerk, and was the head and front of the conspiracy. He was discharged in 1892, and since then, it would be shown, had, with the aid of the other defendants, been carrying on a fraudulent business by forging the name of the Edison-Swan Company upon lamp-holders resembling those manufactured by the Company. Attride was accused of having had a circular stamp made, at the instigation of Ingold, and Cosgrave would be shown to have used a stamp belonging to Messrs. Paterson and Cooper, electrical engineers, of Pownall-road, Dalston, E. Cosgrave had been employed by Paterson and Cooper (who were licensed by the Edison and Swan Company to stamp lamps and sell them), and he had taken the stamp home and used it. In addition to this stamp, which had been used in these fraudulent transactions, there was the stamp which was made for Attride by a stampcutter at St. Luke's. Ingold had a number of incandescent electric lamps made in Germany, and after these had been stamped they were sold at less than half the price at which such lamps were sold by the Edison and Swan Company. After the opening statement of counsel, the evidence of Walter Finlay, an electrician, formerly in the employment of the Edison and Swan Company, was taken. He said he left the Company's service in 1892. He had since then, at Ingold's request, obtained consignments of lampholders from a maker at Cologne, and Ingold paid him for acting as agent.

The further hearing was then adjourned.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HAND-BOOK is in active preparation, and orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. The usual circulars, &c., are now being sent out. Full particulars post free on application.

TENDERS INVITED.—The Corporation of Durban invite tenders for the supply, and for delivery and fixing at Durban, of steam and electrical plant (high-speed steam engines, dynamos, cables, arc and other lamps, accumulators, &c.). Specifications and plans can be obtained from the consulting engineer to the Corporation, Mr. W. H. Radford, Angel-row, Nottingham, and tenders (in duplicate) must be delivered at the offices of Messrs. Webster, Steel and Co. (agents to the Corporation), 5, East India-avenue, London, E.C., by the 28th inst. Further particulars appear in our advertisement columns.

——— The Leyton Urban District Council require tenders for electric lighting works, including central station buildings, gas engines, travelling cranes, piping, &c., dynamos, switchboards, &c., storage batteries, and five miles of mains, including laying. Tenders to Mr. R. Vincent, clerk, Town Hall, Leyton, Essex, before 6 o'clock on *Tuesday next*.

——— The Guardians of St. Luke, Chelsea, require tenders for the fitting up of an electrical wiring installation, including fittings, in the Chelsea Infirmary extension, Cale-street, Chelsea. The specification and form of tender can be obtained from the 17th to the 28th inst., inclusive, from the architects, Messrs. Lansdell and Harrison, 12, Compton-terrace, Highbury, London, N., and tenders must be sent in to Mr. Wm. Miller, Clerk to the Guardians, at the offices, 250, Kings-road, Chelsea, S.W., by noon of December 31st. Some further particulars are given in our advertisement columns.

TENDERS INVITED.—Particulars may be obtained at the Brazilian Consulate in London, Liverpool, Manchester or Glasgow of tenders required for lighting the city of Pernambuco by electricity, which are invited by the Government of the State of Pernambuco, Brazil. Some particulars are given in our advertisement columns.

——— The City Council of Aussig-a.-d.-Elbe invite proposals for the construction of about 11 kilometres of tramways. Tenderers may provide for electric or other motive power in their schemes. Tenders to the Bürgermeister, Aussig, Germany, by January 31st.

——— The Manchester City Council invite tenders for wiring, and for the supply and erection of accumulators, columns and lamps for the electric lighting of the Foreign Animals Wharf, Mode Wheel. Tenders, addressed to the Chairman of the Markets Committee, must be delivered at the Town Hall, Manchester, by 10 a.m. on the 20th instant.

——— The Cleator Moor Co-operative Society require tenders for an electric light installation at their central stores. Particulars from the Secretary, Mr. J. C. Teasdale, Cleator Moor, Cumberland.

——— Tenders are being invited by the Wallassey District Council for installing the electric light at the Seacombe, Egremont and New Brighton Ferries. Tenders to the Chairman of the Ferry Committee, Public Offices, Egremont, by 4 p.m. on Monday next.

——— The Municipality of Ploesti invite tenders for lighting 46 of the principal streets in the centre of the town by electricity. Particulars from La Mairie de Ploesti, Roumania.

——— The Belgian Minister of War invites tenders for the electric lighting of the new military school in the Avenue de la Renaissance, Brussels. Tenders to the Ministère de la Guerre by January 15th.

——— The General Direction of the Belgian Posts and Telegraphs invites tenders for the supply of 11,692 telegraph poles. Tenders to the Direction Générale des Postes et Telegraphes, Brussels.

——— The Alsace-Lorraine State Railway authorities are inviting tenders for the supply of 1,010 telegraph poles. Tenders to the Betriebs-Direktor der Reichs Eisenbahnen, Strasburg.

——— The Prussian State Railway telegraph authorities at Saarbrücken invite tenders for the supply of 28 normal sets of Morse telegraph apparatus. Tenders to the Eisenbahn Telegraphen Inspektion, Saarbrücken, Germany, by the 16th instant.

——— The Mayor of Charkow (Russia) invites tenders for the supply of steam engines and electrical machinery and apparatus necessary for an electric light installation capable of supplying current to 6,000 incandescents and 500 arcs.

——— The General Consul of the South African Republic invites tenders for the delivery of 5,000kg. 2mm. hard drawn copper wire for the Telegraph Department of the Republic. Conditions, &c., from Messrs. Belinfante Bros., Paveljoensgracht, The Hague, and tenders must be sent in to the Consul, at the American Hotel, Leidsche Plein, Amsterdam, by December 20th.

TENDERS ACCEPTED.—The Eccles Town Council have decided to accept the tender of the Manchester Edison-Swan Company for the supply of machinery, &c., in connection with their electric lighting scheme for £13,792.

——— At the last meeting of the Metropolitan Asylums Board the South-Western Committee reported that they had accepted the tender of the Private Wire and Telephone Installation Company for fixing fire alarms and electric bells at the new administrative block for £71. 6s.

——— The Electric Lighting Committee of the Belfast Corporation have accepted the tender of Messrs. J. H. Holmes & Co. for the supply of electrical instruments, and of Messrs. Gill and Russell for iron pipes for their electricity works.

——— The Improvement Committee of the Sheffield Corporation have accepted the tender of the Sheffield Electric Light and Power Company for wiring the Town Hall for the electric light at £720. The tender of Messrs. W. Singer & Sons, of Frome, for supplying and fixing the electroliers at £1,028, has also been accepted.

——— The contract for wiring and fitting up Messrs. Metcalf and Kirkpatrick's premises, Wellington-place, and also the Kentish Hotel, Tunbridge Wells, has been given to Mr. F. Bruce, Hastings.

——— The Stafford Town Council have accepted the tender of the Stanton Ironworks Company for laying steam piping between the boiler houses at the electricity works and the neighbouring gas works for £65 12s. 6d. The tender of the Smethwick Boiler Covering Company, for covering the pipes with non-conducting composition at £38, has also been accepted.

TENDER RECEIVED.—Three tenders received by the Dundee Town Council for wiring and fitting up the Lochee Free Library and Baths for the electric light have been referred to the Lord Provost and the architect of the buildings for consideration.

Digitized by Google

EXPERT SERVICES REQUIRED.—The Guardians of Mile End Old Town contemplate lighting their municipal establishments by electricity, and are open to receive from consulting electrical engineers proposals for supervising the work, including the preparation of specifications, plans, &c. Some further particulars are given in our advertisement columns, and proposals must be sent in before the 19th inst. to Mr. W. Thacker, Clerk, Guardians Offices, Bancroft-road, London, E.

APPOINTMENT.—Mr. Francis G. Baily, M.A., Cantab., for some time Lecturer in Electrotechnics at University College, Liverpool, has been appointed to succeed Prof. R. Mullineux Walmsley at Heriot-Watt College, Edinburgh.

VACANT APPOINTMENTS.—As will be seen from our advertisement columns the Vestry of St. Mary, Islington, have vacancies for three electricians (salary £2 per week), one foreman fitter, and a number of workmen in connection with their electricity supply scheme. Written applications have to be sent in addressed to the Electrical Engineer, Electricity Department, 50, Eden-grove, Holloway, London, N., by twelve o'clock noon of Monday, the 16th inst.

CHANGE OF ADDRESS.—The North of England branch office of the General Electric Company (Limited) is removed from 21, Grainger-street West, to 13, Westgate-road, Newcastle-on-Tyne.

REMOVAL.—Messrs. W. F. Dennis and Co., the well-known agents for Messrs. Felten and Guilleaume and for the Antwerp Telephone Works, are removing from No. 11 to No. 23, Billiter-street, London, E.C.

DISSOLUTION OF PARTNERSHIP.—Messrs. R. L. and S. L. Baxter and D. J. Macdonald, hitherto trading as mica merchants at 81, Murraygate, Dundee, have dissolved partnership. Debts by Messrs. R. L. and S. L. Baxter.

THE "DOVETAIL" DYNAMO AND MOTOR BRUSH.—Messrs. F. W. Potter and Co. send us illustrated particulars of the "Dovetail" copper gauze brush for dynamos and motors made under Soar's patent, for which, it is claimed that they are not stitched, do not

FIG. 1.

wear oval at the commutator, do not turn up at the points, and require a minimum of attention. The "Dovetail" brush is so folded that the part intended to face the commutator consists of plain layers of gauze to the extent of about one-half of the thickness

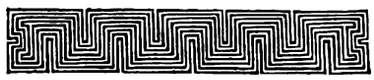

FIG. 2.

of the brush, backed by about an equal quantity of gauze folded or corrugated at or nearly at a right angles to the plain layers as shown in Fig. 1, or without the plain layers as in Fig. 2, and the degree of stiffness given to the brush can be varied to almost the rigidity of metal.

TIME-CHECKING CLOCKS.—We have received particulars from Messrs. F. Brook and Co., of Huddersfield, of Brook's patent "Paragon" automatic time-checking clock, which consists of mechanism for recording the arrival and departure of workpeople by means of the automatic disposal of workpeople's checks according to their punctual or late arrival and departure from the works. These clocks can be worked either by electricity or clockwork. If by electricity, the clock can be fixed in the office, or at any conspicuous part of the works, and any number of time-checkers can be accommodated from it. This arrangement is specially devised for large works, where there are several workpeople's entrances.

"CASSIER'S MAGAZINE."—An excellent number of this popular American magazine is issued for December. The articles include "The Evolution of the Portable Engine," "Electric Power in Collieries," "Power Consumption on Electric Railways," "Some American Vertical Boilers," "False Economy in Foundry Equipment," and some interesting reviews under the heading of Current Topics. Several of the articles are well illustrated, and the magazine is, as usual, well printed on good paper.

CALENDAR.—We have received from the Direct United States Cable Company a useful hanging pad calendar for 1896.

TOBIN BRONZE.—This elegant and artistic name is given by the Ansonia Brass and Copper Company, of New York, to an alloy which they manufacture for engineering purposes. The merits of this material are set forth in a tobin-bronze-coloured pamphlet, a copy of which we have recently received. The alloy appears to possess great tensile, crushing and torsional strength; and in addition those properties of elasticity, &c., which are essential to a material intended for use in engineering constructive work. Among other things, tobin bronze has been found useful for making drop-forged commutator segments.

HEATHMAN'S LADDERS.—A new catalogue just issued by Messrs. Heathman and Co., of Endell-street, Shaftesbury-avenue, W.C., will be found to contain useful information for companies and local authorities engaged in public lighting. Ladders manufactured by this firm are largely used in the cleaning and tending of public lamps in London and several towns in the provinces.

ABERDEEN.—The offices of the Northern Assurance Company in Union-terrace have just been fitted up for the electric light. About 100 incandescents are employed, and the fittings throughout the building are of artistic design. The other tenements in the building are also wired, the entire contract having been entrusted to Messrs. Shirras, Laing and Co.——Experiments are being made with a view to the adoption of suspended overhead street arcs in the principal thoroughfares of this city. It has been arranged that several lamps shall be suspended at distances of about 60 yards as a trial.

ADELAIDE (SOUTH AUSTRALIA).—Some time back the Corporation of this city decided to make experiments in electric lighting in the public streets, and early in November practical effect was given to this resolve. The arc lamps are Crompton's make, and have been erected by Messrs. R. W. Thomson and Co., of Leigh-street, Adelaide, current being supplied from the same firm's supply station at Bank-street, from which the theatre, a number of hotels and many of the principal shops in the city are now supplied with current.

BATH.—At the last meeting of the Urban Council it was decided to form a special Electric Lighting Committee.

BURSLEM.—The North Staffordshire Tramways Company have entered into an undertaking with the Burslem Town Council to make extensions to their tramway system in different districts within two years.

BUXTON.—At the meeting of the District Council on Friday the Electric Lighting Committee's report stated that it was undesirable to instal the electric light in Buxton at present. The Council obtained a Provisional Order in 1894, and the Committee have been considering the electric lighting question for some time past. Evidently it is intended to proceed leisurely in the matter, and to do nothing "rash or injudicious."

CHELTENHAM.—The Electric Lighting Committee report that applications for current are coming in in a very satisfactory way from all parts of the town. Some extensions will shortly have to be made—notably to Leckhampton, from which district an offer has come from Mr. Harold Webb, who agrees to wire for the electric light a number of workmen's houses he is building if the Committee will put in prepayment meters. Mr. Norman, in referring to this offer, stated that this was the first indication of a change which the Committee were very anxious to adopt, and which will, he anticipates, lead to a considerable increase in the consumption of current amongst tenants of the smaller houses. A number of Brush-Vienna arc lamps and transformers have been ordered by the Committee. The number of lamps applied for equals 5,120 8 c.p., and of these 4,300 are wired. It was originally anticipated that 5,000 lamps would be connected up by Christmas. It is now estimated that this number will be 6,000.

CHINESE TELEGRAPH CABLES.—The Chinese Telegraph Administration has recently laid a cable from Yangtse to Tsungming, and communication with that important island is shortly to be opened.

COLWYN BAY.—At the last meeting of the District Council Mr. W. Davies moved that the Council oppose the Dissolution and Re-incorporation Bill of the local gas company, and that the Council's application to the Board of Trade for a Provisional Electric Lighting Order be proceeded with. Mr. J. Roberts moved that the Council ascertain the views of the ratepayers as to the purchase of the gas undertaking, and that no opposition be made to the Company's application to Parliament. After a long and acrimonious debate the amendment was carried by five votes to three.

DEVONPORT.—The County Council, at a special meeting yesterday, decided to apply to the Board of Trade for a Provisional Electric Lighting Order.

DUBLIN.—It will be remembered that the Dalkey Town Commissioners decided to oppose the application of the Dublin Southern District Electric Tramway Company for powers to extend the electric tramways to Dalkey. After a discussion with Mr. J. Clifton Robinson, C.E., the Managing Director of the Company, the Commissioners, without rescinding the resolution to oppose, have agreed to receive a deputation to again discuss the matter.

ECCLES.—The Property Owners' Association has decided to oppose the Town Council's proposal to spend £20,000 in carrying out their electric lighting scheme.

EDINBURGH.—Prof. A. B. W. Kennedy has just presented a report on the proposed extension of the electric light system in

Digitized by Google

Edinburgh. The report, which recommended considerable additions to the generating plant and mains, was considered and approved by the Electric Light Committee at their last meeting. The Town Council will consider the matter at their next meeting. The Committee report that they have now an equivalent of 46,000 8 c.p. lamps connected, the total number of units sold during the thirty-four weeks' period of supply being no less than 285,000, generated at a cost of 1·56d. per unit sold. Thus, in the first 37 weeks' working all working expenses have been paid and nearly all charges for interest and sinking fund. The total capital expenditure has worked out a little less than Prof. Kennedy's estimates. Considerable additions have, however, been made, both in the station buildings and the mains, which have caused additional expenditure. Prof. Kennedy says: "The result seems to me to have been the best possible justification of the policy adopted by the Town Council in making these extensions. From Mr. Monkhouse's statements to me, and from my own observation of what has been going on in Edinburgh, I can hardly doubt that you must be prepared to supply current to an additional 40,000 or 50,000 lamps at least (beyond those now connected) by next winter. The smallest addition to the plant which would meet the case would be four more machines, each of 225 kilowatts. These, together could provide for 26,400 lamps alight at once, or say 53,000 lamps wired beyond those at present on the circuit. The station could therefore safely supply current for 90,000 to 95,000 lamps wired, including the equivalent of the arc lamps, which number will, no doubt, be reached by the end of 1896; and I think the only question now is whether you should put down four or six new sets at once. These additions are to the continuous current plant. The proposed lamps in Clerk-street and in Leith-walk will be high tension lamps, and if these are sanctioned, two more rectifiers will be required, which will be sufficient for 25 or 30 additional lamps for still further extensions. An additional alternator will be required, and I think ought to be of a capacity about double that of the present ones, or say 160 kilowatts. It would further conduce to economical working if a motor-alternator were provided to be driven by the battery in the day-time, so as to avoid the necessity of always keeping an engine (with boiler) actually at work. The boiler-house is large enough for many more new boilers, of which it is recommended that five be added of the existing type (the Droyback marine). As to mains—the existing feeders, which contain, of course, the heaviest copper, have been laid large enough for about 75 per cent. beyond their present load, so far as they are laid in armoured cable. Those portions of them which consist of bare strip can be nearly doubled in section without moving the roadway or pavement, and at a very moderate cost." Prof. Kennedy then refers to the question of high-voltage lamps, and says that the supply of these has come sooner than was expected. The report proceeds:—"The system which I recommended to you and which you have carried out was chosen so that full advantage could be taken of these new lamps whenever they came on the market. They are already to be had, of satisfactory quality, up to 200 and even 250 volts. I hope, therefore, that before long your system may be changed into a three-wire system, at just double its present voltage, a change which will quadruple the present carrying capacity of the mains, and will involve very little change in the station plant, engines and dynamos." In this connection the question of the existing lamps is a formidable one, and Prof. Kennedy makes the following suggestion:—Let the undertakers give notice (*a*) than on and after a certain date (say February 1st, or, perhaps, May, 1896), their standard voltage will be 230 in respect to all consumers connected after that date; (*b*) that on and after another certain date (say August 1, 1897), the new voltage will be standard over their whole system, new and old; and (*c*) that at any time between those dates the undertakers will supply any existing consumers with new lamps (for 230 volts) at the price of 6d. each, the old lamps becoming the property of the undertakers. The effect of this last clause would be that each consumer would run his existing set of lamps as long as possible, and then buy a new set very cheaply from the undertakers. The undertakers would probably lose about 8d. per lamp on the transaction. Prof. Kennedy estimates the total cost of this change to the Edinburgh Corporation at about £670, plus the wages of men employed in changing the lamps, &c. There are no electrical difficulties in the way of making the change. There are some difficulties in detail as to shops which at present use not more than two arcs, and as to a few motors, but these are small matters which can be easily arranged. After referring to the fact that, owing to savings effected in the estimated cost of previous extensions, additional extensions can be safely sanctioned, the report concludes with a recommendation that a substantial reduction either in the nominal price or in the scale of discounts should take effect from the new year. The Committee, after careful consideration of the foregoing report, recommend that four engines and dynamos low-tension, one engine and dynamo high-tension, two rectifiers, five boilers, and all necessary apparatus be added to the existing plant.

ELECTRICALLY-DRIVEN VENTILATING FANS FOR THE NAVY.—It is stated that experiments are about to be made by the Admiralty as to equipment of vessels with electric fans for ventilating purposes.

ELECTRIC PLANT FOR GOLD MINES.—The Directors of the Sheba Gold Mine Company have recently issued their report to the shareholders, in which reference is made to the extensive plant recently sent out by Messrs. Johnson and Phillips. The Directors state that the laying down of the plant by which power generated at the Queen's River has been transmitted seven miles, was a great experiment, and that the Directors, on the whole, are well satisfied with the result. The first electric plant ran 25 stamps, but was gradually developed to 50 stamps, and motors are now being sent out to deal with a remaining 10 stamps. In addition to this plant electrical machinery is to be erected to supply power for working the new air-compressing plant for ten drills. Arrangements have been made to provide adequate water power to secure the continuous working of the electrical machinery.

FAREHAM.—At the meeting of the District Council on Friday last the result of the recent action at law between the Council and the Fareham Electric Light Company, which was fully reported in our columns, was discussed. A number of ratepayers attended, and the meeting was a very noisy one, which is not unusual at Fareham when the electric lighting subject is discussed. The Chairman of the Council (Mr. W. Pankhurst) now proposes to take a poll of the ratepayers to ascertain their views as to the action to be taken with regard to an appeal. It was decided that before paying the damages awarded, or accepting the offer made in Court by the Company to complete the purchase of the undertaking, that a poll should be taken on December 21st.

FIRE.—A fire broke out on the premises of the Automatic Electric Sign Company, in Swaine-street, Bradford, on Sunday last. The damage was very slight.

FOUNDRY LIGHTING.—The works and offices of Messrs. Dobbie, Forbes and Co., of Larbert, have been fitted up for the electric light. The offices and pattern shops are lighted by means of incandescents, while arcs are employed for lighting the main arteries of the moulding shops and furnace, thus allowing the somewhat dangerous process of running the bogie ladles with less risk of accident. A very ingenious arrangement has been applied in part of the moulding shops, the invention of Mr. T. Laurie, whereby each moulder can traverse his lamp from end to end of his "row," move it up or down, and bring it to project the light on any part of his work. The installation has been carried out by Messrs. T. Laurie and Co., of Falkirk.

FULHAM (LONDON).—A special meeting of the Vestry was held last week to consider the advisability of applying to the Board of Trade for a Provisional Order. Mr. Sayer (the Chairman of the Electric Lighting Committee) said that, while he was prepared to move that the Vestry apply for a Provisional Order, they could not take action until November or December next. They had engaged an electrical expert to advise them, and had decided to oppose the Capital and Counties Electricity Supply Company's application for an Order. Under the circumstances he thought it would be unwise to proceed to a vote, and he moved that the question be adjourned for three months. The matter could be considered when they had received their electrical engineer's report, and they would not prejudice their position by adopting this course. An amendment to adjourn the matter for six months was moved by Mr. Marks, and after some discussion was carried.

GREAT YARMOUTH.—The Town Council have unanimously decided to increase the salary of their electrical engineer (Mr. A. W. Ranken) to £200 per annum. The surveyor's report, presented at the last meeting of the Council, gives evidence of the continued progress of the electric light undertaking, and of the steady increase in the demand for current. During the past month there were fresh applications for 580 8 c.p. lamps, bringing the total number of lamps applied for up to 6,369. The income for the month was £308. 8s., and the working expenses £164. 14s. 2d., a gross profit of £143. 13s. 10d., from which, however, £90 has to be deducted for repayment of capital, interest, depreciation, &c. Arrangements are being made for supplying current during daytime.

HACKNEY (LONDON).—On Tuesday the reports of the Electric Lighting Committee appointed some months ago, and of the consulting engineer to the Vestry, Mr. F. H. Medhurst, were considered. The Committee advised strongly in favour of a combined scheme of electric lighting and refuse destruction, such as is proposed by Mr. Medhurst, and are convinced of the accuracy of Mr. Medhurst's estimate for the work. Mr. Medhurst's Report is very exhaustive, and goes with great detail into the scheme, under which it is proposed that current should be sold at 5d. per unit, this low figure being based upon the expectation that Hackney will be able to produce and distribute electric current on a more economical scale than any of its metropolitan predecessors. The dust destructor scheme enters largely into that of the proposed electric light undertaking, as this is estimated to give an output of steam equal to 480 H.P. for the

Digitized by Google

full 24 hours, and although a considerably larger output would be necessary for a small portion of the time, this could be secured by an admixture of coal with the ashbin refuse burnt in the destructors, or, as an alternative, the scheme provides for a battery of accumulators to be charged during the day. Mr. Medhurst's scheme is for an initial installation equivalent to 16,000 8-c.p. lamps, and 140 1,000-c.p. arcs for lighting the main thoroughfares of the district. The high-tension alternating-current system is recommended as the cheapest for Hackney. The area included in the Vestry's order obtained in 1893 represents about four miles of streets, which it is estimated the 140 arcs would efficiently illuminate. For the public electric lighting an allowance of £1,800 per annum is estimated, this being three times the cost of the existing gas lamps, but for this increased outlay a light 16 times greater than the present will be given from dusk to midnight, and eight times greater from midnight to dawn. This increased cost, it is calculated, will be saved several times over by the decreased cost of dealing with the refuse of the district, the saving on 40,000 tons being estimated at £3,500 a year. This and the income from private and public lighting give a total revenue of £10,685. 13s. 4d., against which are set working expenses £5,357, plus a bye-product in the shape of mortar "to be economically manufactured from the waste clinker from the destructors," and such income as could be derived from the supply of current on a day load for motive power purposes, which it is proposed should be sold at 2½d. per unit. The interest and sinking fund account is credited with £4,000 per annum, leaving an estimated clear profit for relief of the rates of £1,328 per annum. The capital outlay in Mr. Medhurst's scheme is limited to £80,000.

HANLEY.—The Local Government Board have sanctioned the borrowing by the Town Council of a further sum of £19,000 for electric lighting purposes.

HARROGATE.—A Local Government Board inquiry will be held on Tuesday next into the application of the Town Council to borrow £27,000 for electric lighting purposes.

HORSELESS VEHICLES *v.* LIGHT RAILWAYS.—At a meeting at the Cannon-street Hotel, on Tuesday, an association was formed to be called the Self-Propelled Traffic Association, to be incorporated under the Companies Act. Sir David Salomons, who presided, stated that the Association had for its objects the encouragement of a new industry in England, "and the conferring of benefits upon the agricultural classes and the struggling professional man." The benefit to the agricultural classes is to be the adoption of the horseless vehicle in place of light railways in bringing garden produce to the distributing centres; the benefit to the struggling professional man was not particularly specified. It is proposed to limit the liability of members to the amount of their £1 shares. Mr. H. J. Lawson, "the inventor of the bicycle," described how he and his friends had scoured the Continent buying up patent rights in connection with the manufacture of the horseless carriage at an expenditure of £100,000, which he urged as evidence that no stone would be left unturned to secure success for the new industry.

HUDDERSFIELD.—At last week's meeting of the Borough Council the Council's Improvement Bill was discussed. The first subject dealt with was the proposed application to the Board of Trade for a Provisional Order to supply electric current to the Longwood district by extending the area of supply regulated by the Huddersfield Order of 1890. This proposal met with the approval of the Council. Although, so far as the electric lighting section of the Improvement Bill is concerned, the feeling of the Council and the ratepayers is favourable, a largely-attended meeting of the Ratepayers' Association had previously met and passed a resolution demanding the withdrawal of the Bill, and after a lengthy discussion the Council decided to adjourn the further consideration of the matter to a future meeting.

ISLINGTON (LONDON).—At the last meeting of the Vestry, Mr. Lambert (the Chairman of the Electric Light Committee) stated that they hoped to be in a position to supply electric current by January 31st next.

KIDDERMINSTER.—Messrs. A. Dickinson and Co., engineers, of Birmingham, have applied to the Worcestershire County Council for permission to construct electric tramways between Kidderminster and Stourport Bridge and between Short Heath and Kidderminster.——The General Purposes Committee of the Town Council have instructed the Borough Surveyor to prepare a written report upon the proposed electric tramway scheme, by which a line is to run through Kidderminster on to Stourport. The necessity of engaging the services of an expert adviser is also to be considered.

KINGSWOOD (BRISTOL).—The District Council had before them at their meeting on Wednesday the proposals of the Great Western Electric Light and Power Company for the electric lighting of the district. The Great Western Company have notified their intention of applying for a Provisional Order. The proposals were discussed at some length, but the Council finally adjourned the matter until their next meeting.

LEEDS.—Mr. Arthur John Vinall, Postmaster at Portsmouth, has been appointed to the Postmastership at Leeds, vacant by the transfer of Mr. Salisbury to Liverpool. The salary is £800 per annum.

LEYTON.—Mr. Rienzi Walton, M.I.C.E., held a Local Government Board inquiry last week into the application of the Council for permission to borrow, amongst other sums, £16,200 for electric lighting purposes. The Council were represented by Mr. R. Vincent (the Clerk) and Prof. H. Robinson, while the application was also supported by Mr. Sutton, Chairman of the Local Tradesmen's Association. Prof. Robinson explained that the generating station would be situated at the back of St. Patrick's Cemetery, Harrow Green, and submitted plans showing the various streets in which it is proposed to lay the mains.

LIVERPOOL.—It is anticipated that before the beginning of the new year the heading of the tunnel at the South end for the extension of the Liverpool Overhead Railway will be driven through from the Herculaneum Dock to the Dingle Terminus, as only about 60 yards have now to be pierced. This extension will widely differ from the original portion of the line. This is carried upon an iron viaduct a good height above the level of the street, but the extension burrows all the way through soft red sandstone rock, and the Dingle Terminus, at which the extension ends, will, with the exception of the ticket and station offices, be below the level of the ground. A new station is to be built upon the existing line opposite the Wellington foot bridge, the end of the existing line being used as a carriage shed. The new station will be conveniently placed for residents in the Toxteth district, as a footbridge is to be erected. When the extension is completed, the northern and southern parts of the populous district along the line of docks will be connected by the electric railway. It is anticipated that the extension will be in full work early in the coming summer.

MADRAS.—Trial trips are now being made on the Madras tramways by Mr. Gadsby, the Company's electrician, on those portions of the new sections which are to be worked by electricity on the overhead system. For some distance (from the power station to Chintaripet) the electric cable is taken underground and joins the main line at the latter place; from thence it is carried overhead. The cars running on this section are to be lighted by electricity. Portions of the line are ready for working at once, but will not be worked until the lightning arresters are fitted.

MARGATE.—At their last meeting the Town Council, on the motion of the Mayor, decided to apply to the Board of Trade for a Provisional Electric Lighting Order.

MEVAGISSEY.—At the last meeting of the District Council a Committee of the whole Council was appointed to confer with the engineer of the Mevagissey Electric Lighting Company as to the most suitable positions for the street lamps.

NEWPORT (SALOP).—The District Council have appointed a committee to consider and report upon the question of adopting an improved system of lighting.

NEW PREMISES.—The Lighting Corporation (Limited) have secured Bedford Chapel, New Oxford-street, W.C., so well known in connection with the preaching of Mr. Bellew and of the Rev. Stopford Brooke, on an 80 years' lease from the Duke of Bedford.

OLDHAM.—The Oldham Corporation have decided to increase the salary of their electrical engineer (Mr. S. Wilmott Newington) from £160 to £200 per annum.

PAISLEY.—The Electric Lighting Committee of the Town Council have had under their consideration the advisability of either proceeding with the electric lighting of the town in terms of their Provisional Order, or of entering into an agreement with the Caledonian Electric Supply Company for a transfer of the Order. At the last meeting of the Committee the Provost stated that, so far as he was able to ascertain, there was at present no demand in the town for the electric light, and this view being concurred in by the Council, it was decided not to proceed further in the matter.

PERTH.—The Police Commission have some spare power at their disposal, and notice of motion has been given for the next meeting of the Commission that it be remitted to a Special Committee to consider and report as to how this power could be best utilised, and especially with a view to the electric lighting of the Corporation Buildings.

QUEENSTOWN.—At a special meeting of the Town Commissioners a resolution that application be at once made to the Board of Trade for a Provisional Order was carried with only one dissentient. This means business, as, in addition, the Commissioners gave instructions to the Clerk to draw a cheque for £50 for the statutory fee.

ROYAL ALBERT AGED MERCHANT SEAMEN'S INSTITUTION.—An earnest appeal is made on behalf of the funds of this Institution, in which the late Sir James Anderson took so great an interest. There are many members of the cable fleet stationed throughout the world who may read these lines, and if they, or any of our readers, can spare a contribution to the funds, grateful acknowledgment will

Digitized by Google

be made by the Secretary, Mr. W. E. Denny, 58, Fenchurch-street, London, E.C.

SHREWSBURY.—The formal opening of the Shropshire Electric Light and Power Company's electricity station took place on Tuesday last. The station has been equipped by Messrs. Edmundsons (Limited) to the plans of Mr. A. H. Preece, the Company's consulting engineer. The plant consists of three 60 I.H.P. Babcock-Wilcox boilers, three Belliss engines, and three continuous-current Parker dynamos. A battery of D.P. accumulators has also been put in, and the mains have been supplied by the Callender Company.

SMITHFIELD CLUB SHOW.—As usual, the attendance at this Show during the week has been enormous, and the opportunity of bringing electrical appliances of a domestic nature before this immense number of visitors has, also as usual, not been made the most of. It is estimated that not far short of 150,000 persons visit the Agricultural Hall during the "Cattle Show" week, and amongst this number must be hundreds to whom the possibilities of small electric light and power plants are practically unknown. We were surprised not to find Messrs. Crompton and Co. at the Hall with their heating and cooking apparatus, and there are several firms who could be mentioned whose artistic fittings and electrical novelties might have been effectively, and doubtless remuneratively, displayed. Although electrical exhibits were noticeable by their absence, the same cannot be said of the exhibits of the leading engine and implement builders, whose displays gave the Show an attractive and busy appearance. Traction engines, threshing machines, and similar machinery can have but little interest for a fair proportion of the visitors to the Agricultural Hall, but it is always interesting to watch the crowds which congregate wherever these machines are displayed, and who are evidently impressed when inspecting a more than usually imposing specimen of the engine builder's work. In this respect the centres of attraction at this year's Show were the exhibits of Messrs. Robey and Co.; Ransomes, Sims and Jefferies; Marshall, Sons and Co.; Clayton and Shuttleworth; John Fowler and Co.; E. S. Hindley; and Crossley Bros. At the stands of these well-known firms a splendid array of engines, agricultural machinery, &c. were on view. Messrs. W. H. Willcox and Co. displayed a great variety of engineers' stores, belting, &c.

SOUTHPORT.—At the last meeting of the Town Council Mr. W. H. Herford brought forward an electric light extension scheme, but after discussion it was agreed to postpone the matter for a month.

SOUTH SHIELDS.—Alderman Rennoldson, in presenting the report of the Electric Lighting Committee to the Town Council at its last meeting, made reference to certain deviations which had been made from the original scheme, but which had not entailed any additional expense, owing to savings in other directions. He referred to the low price at which it was proposed to supply current—6d. per unit—and the advantage which would accrue to large consumers, who would be able to reduce the cost of their electric current by 15 to 20 per cent. Notwithstanding a very determined opposition to the Committee's report, it was voted by a large majority, the Committee being complimented upon the results of their labours.

SOUTH STAFFORDSHIRE TRAMWAYS.—The South Staffordshire Tramways Company have been notified by the Electric Construction Company that the agreement between the two companies for the working of the electrical portion of the tramway lines at Walsall will not be renewed after the end of the current year unless the road bed is put in reasonably good repair. The Construction Company provide the motive power, the cars and drivers, and own the generating station and machinery. The matter is one of great importance to residents in the Wednesbury, Darlaston, Walsall, and Bloxwich districts, and the travelling public generally will hope that satisfactory arrangements will be come to before the expiration of the time stated. The Construction Company wish it to be distinctly understood that they have no desire to stop the running electric cars if arrangements can be come to for their continuation, and that it is not they who are putting obstacles in the way. The Company undertook to run the electric cars at a certain price per mile, the roads to be kept in a satisfactory state by the tramway company. The roads are now in a most unsatisfactory condition, indeed, are so bad that unnecessary wear and tear to the cars and machinery are caused. During the last year or two the cars have been run with great regularity and punctuality.

ST. AUSTELL.—At the last meeting of the District Council the Lighting Committee were instructed to prepare a specification on which the local electric light and gas companies might be invited to tender for the lighting of the principal streets.

ST. PANCRAS (LONDON).—At the last meeting of the Vestry it was decided to reduce the price of current for churches and chapels to 5d. per unit. Mr. Bangs, a governor of University College Hospital, stated that the authorities of that institution desired to substitute electric lighting for gas, and asked that they might have the current at the reduced charge. The matter was referred to the Electricity Committee.

SUNDERLAND.—At the last meeting of the Highways Committee Mr. C. S. Vesey Brown's report on the proposed electric lighting extensions was considered and approved. These extensions are rendered necessary by the increasing demands for current, and are estimated to cost about £13,750. Mr. Vesey Brown estimates, when these extensions have been carried out, the entire cost of generating current, &c., will be 4·20d. per unit, and the probable average charge 5d., showing a profit of 0·8d. per unit, which on an output of 250,000 units amounts to about £835. The capital expenditure to September 30th was £29,483. A loss of £900 has been made on the first year's working, but this is partly owing to the fact that the generating machinery has not been worked to its utmost capacity, and also because the interest and sinking fund charges were somewhat higher than was at first anticipated.

THE BRAZILS.—A considerable extension of the State telegraphs from Maranhao to the town of Palma, in the State of Govaz, has been decided upon, and a credit of $200,000 has been approved.

WALLASEY.—At the last meeting of the Urban District Council the Gas and Water Committee's minutes stated that the engineer had submitted his report on the electric light question. The cost of the buildings, machinery, mains, &c., is estimated at £12,500.

WELLS.—Last week we chronicled the fact that the City Council had decided by the casting vote of the Mayor to offer £14,000 for the local gas company's works, and a special meeting of the Council was held on Wednesday last to receive the Company's reply. The Company, however, declined to accept £14,000, but offered to sell their undertaking for £15,000. The Council have now decided to increase their offer to £14,700 on condition that it is accepted by Monday next. This spirit of compromise is refreshing, and should be rewarded by success.

WEST AUSTRALIA.—The work of duplicating the telegraph line between Perth and Kalgoorlie is now almost complete. The wire passes through the Coo'gardie gold district.

WEYBRIDGE.—At the last meeting of the District Council it was reported that the Weybridge Electric Supply Company had agreed to transfer their Provisional Order to the Council for £100. The Council, however, desire to obtain an assurance from the Board of Trade as to the exclusion of competitors before they make any payment. A committee of the Council are to again confer with the Company on the matter.

WOLVERHAMPTON.—The Town Council have received the formal sanction of the Local Government Board to borrow £5,000 for electric lighting extensions.

YEADON.—The District Council have decided to make a canvass of the ratepayers in order to ascertain the amount of support likely to be given to their proposed electric lighting scheme.

MUSICAL.—Mr. T. E. Gatehouse gives a violin recital at the South London Institute of Music, Camberwell New-road, London, S.E., on Tuesday evening next. An excellent programme is provided, and the concert will doubtless prove as great a success as so many of its predecessors have done under Mr. Gatehouse's direction.

ELECTRIC LIGHTING IN RAILWAY CARRIAGES.

On Tuesday last a meeting of the Preference stockholders of the Great Eastern Railway Company was held at the Cannon-street Hotel, when, amongst other matters, power was asked to raise £250,000 additional capital, of which it was proposed to spend £20,000 for electric lighting.

Lord CLAUDE HAMILTON, who presided, explained that the money to be expended for electric lighting was for the lighting of Bethnal Green Junction and Spitalfields Market. As they were aware, they could work goods traffic much more expeditiously by means of the electric light than by the old system of gas.

Mr. CUSTANCE asked if the electric lighting was to be applied to the carriages, as there was also an expenditure of £20,000 asked for gas.

The CHAIRMAN explained that they had no electric lighting in their carriages.

Mr. CUSTANCE said there were several lines which had electric light in their carriages, and it seemed to him that if they put gas in the carriages now they would be called upon hereafter to construct them for electricity. He would like to know if the matter had been considered by the Board in order to save expense hereafter.

The CHAIRMAN said that for some years they had very carefully considered the question of electric lighting in carriages as against gas, and they found the expense of the electric light far too great for them to attempt to undertake it. There was another objection to electricity for their line. Electrically lighted trains were all very well if the train was made up at the commencement of the journey and in no way dissevered throughout the journey, but, owing to the large number of junctions on their system, their trains were being constantly taken to pieces, and that would interfere with the electric light. Another matter was that the consensus of opinion of the great railway companies was, so far, in favour of gas rather than electric light for carriages.

Digitized by Google

NEW COMPANIES, STATUTORY RETURNS, &c

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, *pages 304-332, &c., &c.*

BRITISH TUBE COMPANY (LIMITED).—This Company has been registered, with a capital of £250,000, in £10 shares, to acquire the business of the British Seamless Steel Tube Company (Limited), Smethwick Works, Birmingham, and to carry on business as iron and steel tube manufacturers, engineers and metal founders.

ELECTRIC INSTALLATION SYNDICATE (LIMITED).—This Company was registered on December 5th with a nominal capital of £5,000, in shares of £10 each, to carry into effect an agreement between Alfred J. P. Whitaker, accountant, and Frederick G. Treharne, analyst, both of Cardiff, and George P. Tutcher (acting for the Company) for the acquisition of the benefit of certain existing inventions, particulars of which do not transpire, and to use, exercise, develop, grant licences in respect of, sell, deal with or otherwise turn to account any such patents, licences, concessions, &c. The first subscribers, with one share each, include: The Duchess of Marlborough, Lord William Beresford, V.C., John W. Palmer, W. Thomas Lewis, Alfred J. P. Whitaker, W. H. Mathias and Frederick G. Treharne. The first Directors are: Lord William Beresford, V.C., Edward Davies, William H. Mathias, Frederick G. Treharne and Alfred J. P. Whitaker.

IMPROVED PATENT FORCED DRAUGHT FURNACE SYNDICATE (LIMITED).—This Company was registered on December 3rd with a capital of £2,000, in £1 shares, to deal with certain letters patent relating to an invention of an improved device for equalising the forced draught for destructor and other furnaces. The first directors are Robert Gosling and James F. Colyer.

WINDSOR ELECTRICAL INSTALLATION COMPANY (LIMITED).—This Company was registered on December 5th with a capital of £10,000, in £1 shares, to acquire and take over as a going concern the business of the Windsor Electrical Installation Company, now carried on at Windsor and the neighbourhood, and to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity for light, heat, and motive power, electrical contractors, electric lamp arch builders, electrical carriage builders and fitters, and the general business of an electric light, heat and power supply company. The first subscribers, with a share each, are local tradesmen.

WOKING ELECTRIC SUPPLY COMPANY (LIMITED).—This Company was registered on December 5th with a nominal capital of £20,000, in £1 shares, to carry into effect an agreement between Anthony G. New and Arthur J. Mayne, electrical contractors, and the Company, to carry on in the parish of Woking and the neighbouring parishes the business of an electric lighting company in all its branches, to construct, lay, establish, fix and carry out all necessary wires, lines, accumulators, lamps and works, and to carry on the business of electricians, electrical and mechanical engineers and contractors, suppliers of electricity for the purposes of light, heat, motive power and otherwise, and manufacturers of and dealers in all kinds of electrical apparatus and appliances. The first subscribers, with one share each, are: Edward Mann, electrical engineer; Charles E. Masterman civil engineer; William J. Rundle, electrical engineer; Charles G. Bromfield, electrical engineer; Frank Wright, clerk; W. W Norman; Arthur Branch, electrical engineer; and Arthur E. D.

ALUMINIUM COMPANY (LIMITED).—The annual return to November 11th, has been filed. Nominal capital £80,000, in 60,000 "A" and 20,000 "B" shares of £1. The latter have been issued as fully paid, and the former paid for in full.

AMAZON TELEGRAPH COMPANY (LIMITED).—The statutory return to November 14th has been filed. The whole nominal capital of £250,000, in £10, shares has been subscribed, and calls amounting to £8 per share have been made. The calls paid (including calls paid in advance on 984 shares) amount to £145,368, leaving £56,600 still in arrears.

G. E. BELLISS AND COMPANY (LIMITED).—This Company's annual return has been filed. The nominal capital is £150,000, divided into 5,000. Preference and 10,000 Ordinary shares, all of £10 each. 4,100 of the former and 6,270 of the latter have been taken up, and 4,098 Preference have been issued as fully paid. The full amount has been called on the two Preference, and a call of £5 per share has been made on the Ordinary shares, resulting in the receipt of £31,370.

ELECTRICAL COAL-CUTTING CONTRACT CORPORATION (LIMITED).—The annual return to November 12th has been filed. The capital is £402,000 in 60,000 Ordinary and 20,000 Deferred shares of £5 each, and 2,000 Founders' shares of £1 each. 9,531 Ordinary and all the Deferred and Founders' shares have been taken up, and 4,000 Ordinary and the Deferred shares have been issued as fully paid. The full amount has been called on the remaining 5,531 Ordinary and the Founders' shares, and £28,375 paid thereon, leaving £1,280 in arrears.

GENERAL ELECTROLYTIC PARENT COMPANY (LIMITED).—The annual return to November 6th has been filed. The nominal capital is £30,000, in £1 shares, and 24,458 of these have been taken up; 18,000 have been issued as fully paid, and the full amount has been paid on the remaining 6,458 shares.

HARROW ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The statutory return to November 19th has been filed; 1,686 shares have been subscribed for out of a capital of £225,000, in £5 shares, and £2 per share has been paid.

LIGHTING CORPORATION (LIMITED).—The statutory return has been filed. The nominal capital is £275,000, divided into 250,000 Ordinary shares of £1 each and 25,000 Preference shares of similar value. Seven Ordinary shares have been subscribed for, and £7 has been paid.

MONTE VIDEO TELEPHONE COMPANY (LIMITED).—The annual return to November 14th has been filed. The capital is £220,000, in 29,000 Preferred and 15,000 Ordinary shares, of £5 each. 28,000 Preferred and all the Ordinary have been taken up, and 3,000 of each class have been issued as fully paid. Full amount called on remaining 25,000 Preferred and 12,000 Ordinary, and £185,000 paid.

WESTINGHOUSE ELECTRIC COMPANY (LIMITED).—The annual return to October 29th, has been filed. The capital is £600,000, divided into 30,000 Preferred and 30,000 Ordinary shares, of £10 each. 18,955 of the former and 27,500 of the latter have been taken up, and 15,000 Preferred and all the Ordinary have been issued as fully paid. Full amount called on 1,835 Preferred, and a call of 10s. per share has been made on the remaining 1,320 Preferred, resulting in the payment of £19,010.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 30d. per oz. (Dec. 12th). Consols (2¾ per cent.) 106⅜ - 106⅞ for money, 106 13/16—106 15/16 for account; 2½ per cent. 104—104¼ (Dec. 12th). Stock Exchange Settling Days: Consols, Jan. 3rd; Stocks and Shares Continuation Day, Dec. 13th and 27th; Ticket Day, Dec. 14th and 28th; Pay Day, Dec. 16th and 30th. Mining Share Carry-over Day, Dec. 24th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended December 8th were £977, against £941 in the corresponding week of 1894, an increase of £36. The total receipts for the half-year amount to £20,527, against £20,518 for the corresponding period of 1894, an increase of £9.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on January 14th next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum, on the Preference shares for the quarter ending December 31, 1895, and the usual interim dividend of 2s. 6d. per share on the Ordinary shares, free of income tax, in respect of profits for the quarter ended September last. The transfer books will be closed from the 7th to 14th January inclusive.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the quarter ended September 30th last, of 2s. 6d. per share, free of income-tax, payable on the 15th prox. The share register will be closed from the 7th to the 14th prox., both days inclusive. The coupons on the Company's Five per Cent. Australian Government Subsidy Debentures, due on January 1st next, will be paid on and after that date at Messrs. Barclay, Bevan and Co.'s bank, 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—The numbers are published of 134 Six per Cent. Second Mortgage Debentures of this Company, which were drawn on the 6th inst., and will be paid on January 1st at the offices of the Electric and General Investment Company, 1 and 2, Great Winchester-street, E.C. Coupons must be left four clear days for examination.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The transfer books and register of members of this Company will be closed from the 16th to the 28th inst. inclusive, in order that warrants may be prepared for the interim dividend on the Ordinary shares. The Directors have declared an interim dividend on the capital paid up on the Ordinary shares of the Company at the rate of 10 per cent. per annum for the six months ended November 30th, payable on and after the 23rd inst.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 8th inst. amounted to £1,042. The amount for the corresponding week last year was £855, an increase of £187.

"MOTOR" AKTIEN-GESELLSCHAFT FUR ANGEWANDTE ELEKTRICITAT. This is the title of a Company which was recently formed in Baden, Switzerland, by the Allgemeine Deutsche Kreditanstalt of Leipzig; Brown, Boveri and Co., of Baden; the Aktiengesellschaft Leu and Co., of Zurich, and other Continental firms. The nominal capital of the Company is 3,000,000fr., of which 20 per cent. is paid up. The Company is established to financially assist electrical undertakings, and will also undertake the exploitation of electrical or electro-chemical works in any part of the world, in the execution of which the Company are to have the assistance and co-operation of Brown, Boveri and Co.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered 25,000 shares (Nos. 1 to 25,000) of the Amazon Telegraph Company (Limited), and the further issue of 3,723 Ordinary Shares (Nos. 10,278 to 14,000) of the Chelsea Electricity Supply Company (Limited), to be quoted in the official list.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ending December 6th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,978.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—At the adjourned ordinary general meeting of the shareholders of this Company, held at Eccleston-place on Wednesday (Mr. J. H. Powell, in the absence of Lord Suffield, owing to illness, presiding), it was resolved: "That, in order to save the trouble and expense of a double yearly audit, it be, and is hereby, resolved that the auditor appointed by the Board of Trade for the official audit should also act as the shareholders' auditor."

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 918. [Vol. No. 8. XXXVI.] FRIDAY, DECEMBER 20, 1895. PRICE SIXPENCE.

NOTES.

THE breaking of eggs is essential to the making of omelettes, and courage, foresight, organisation, and tact are no less essential to the success of a revolutionary resolution such as that brought forward by Mr. RAWORTH at the Annual General Meeting of the Institution of Electrical Engineers last week. There is an evident desire among the members of the Institution that means should be devised to make the Council as representative of the youth and energy of the electrical profession as it admittedly is of its eminence and dignity; and there appears also to be a general consensus of opinion that the best way to obtain this end is to veto the voting power of of the past presidents, and tomake it a rule that the Council list shall be sent out in sufficient time to enable counter proposals to be made, and effectually made. Recent events have amply justified the existence of this hankering after reform, and the devices just mentioned seem likely to meet the case and—the wishes of the great majority of those concerned.

ALL this was easily ascertainable prior to the Annual General Meeting. Nevertheless, it was thought advisable, without any warning to the general body of members, and without any attempt to obtain their views, to move the appointment of a cut-and-dried Advisory Committee with names complete, the mover leaving his hearers in doubt whether this Council of Twelve was to be a temporary expedient or a permanent feature of the constitution. The proposal, at any rate, had the merit of audacity as it stood, involving as it did nothing less than the resignation of a superseded Council. Subsequent exegesis of the text of the proposer's speech has, however, entirely whittled away this single virtue; nothing in the nature of a resolution or of a vote of censure upon Council was intended. Even so, a carefully arranged plan of campaign, and an avoidance of any appearance of snatching a surprise vote, would have contributed to success and prevented the fiasco that followed, which may possibly wreck a movement having both right and might on its side. It behoves the advocates of reform to take counsel together before the next general meeting, to make sure of their ground, to settle their plan of attack, and above all, to pull together. If the thing is worth doing at all it is worth doing well.

Two series of researches on alternate-current arcs, as yet incomplete, but even now affording useful information, are sketched by Dr. FLEMING and Mr. PETAVEL in our columns this week. The first of these researches relates to the comparative spherical candle-powers of alternating and continuous arcs, when equal amounts of power are expended in them. As the authors observe, the final determination of this question would probably possess only an academic interest, and they have wisely confined their researches to a condition of affairs most commonly occurring in practical lighting. In this case it was found that the mean spherical candle-power for the continuous arc was nearly twice that of the alternating arc. This is a severe handicap in the race for public lighting by these two sources of light; and it would be interesting to know how alternate current lamp makers propose to bring about a more equal efficiency, and what effect, say, a rectifier would have upon the practical relative efficiencies. The second line of research deals with a matter of more analytical and theoretical importance—viz., the space and time distributions of the luminous intensity in an alternating arc. The useful light emitted by the carbons and the purple light of the intra-carbon vapour have been differentiated by a most ingenious arrangement of mechanism. As might have been predicted, the light from the true vapour is intermittent, and falls to zero every cycle. The light from the carbon ends does not, but varies in a complex wavy function between a minimum value and two alternating maxima of widely different values. This complicated variation of the useful light of an alternating arc points to at least one of the causes of its relative inefficiency.

SUNDERLAND is in the enviable position of having an electric light station of 6,000 lamps capacity, and applications from customers for 6,925 lights; and this condition of affairs has been reached within eight months of the starting of the concern. Accordingly the cry is for extension of the plant; and that deus ex Westminster, Prof. A. B. W. KENNEDY, has presented a report showing what should be done. He recommends the addition of two dynamos and steam engines to the low-pressure section, together with one steam-driven set for the high-pressure section. His decision is therefore in favour of steam power; and some of the Sunderland folk, who use gas engines in their local industries, are up in arms. The "local engineers, who knew more about the matter than Prof. KENNEDY," so the County Council was informed, "knew that the modern gas engine was the cheapest motive power extant." A little knowledge, even

Digitized by Google

of local engineering, is a dangerous thing; and the opposition is evidently badly informed as to at least two facts. The first fact is that Prof. KENNEDY's advice may be relied on in regard to much more than the essentially electrical part of the scheme, being as expert in gas and steam engines as in dynamos and cables. Secondly, that it is a dangerous half-truth to state that the gas engine is the cheapest power extant. Prof. KENNEDY himself has shown the Sunderland authorities that what is true of a small station, or of a private plant, is not true of a station where an annual output of 300,000 units is contemplated; and that whatever saving there might be in costs with gas plant would disappear with the extension of the works. Nevertheless, Sunderland has decided to wait.

IT might be thought that a small gas engine would be useful in helping the station through the uncomfortable hours; but it must be remembered that the low-pressure section of the Sunderland system is already well equipped with storage batteries, which render auxiliary gas plant superfluous. In this connection it is interesting to note a Paper on "The Storage Battery or the Gas Engine as an Auxiliary," which Mr. NELSON W. PERRY has recently read before the American Institute of Electrical Engineers. The author endeavours to show that "the gas engine, with fuel gas, would prove a much more economical auxiliary to the central station for taking the peak of the load, and the loads amounting to a fraction of a unit (of plant), than the storage battery." We ourselves do not care to be so dogmatic as this, for the value of both gas power and storage plant is liable to be largely influenced by local considerations; but we believe that circumstances might very well exist, in many stations, which would give the balance of favour to gas engines rather than to secondary batteries.

RUMOUR of a wonderfully light and powerful oil engine, in which an electric spark was made to act in an entirely novel manner, came to us from over the Atlantic a short time ago; and now we hear that the motor, the invention of Messrs. KANE and PENNINGTON, has followed. It is said that, in the form specially constructed for cycle propulsion, 2 effective horse-power can be obtained from a gross weight of engine of about 20lb., the engine shaft making 500 revolutions per minute. This, in itself, is a sufficiently astonishing claim; and we look forward with curiosity to the trials which no doubt shortly will be made by competent English engineers. But a still more surprising feature is the apparent action of what has been termed an electric "mixing" spark. The engine works on the ordinary Otto cycle, and towards the end of the compression stroke an electric non-igniting spark is passed through the charge. It is claimed that the effect of this spark is to complete the vapourisation of the oil, and thoroughly to mix the vapour with the air. A second spark, at the commencement of the working stroke, serves to ignite the explosive mixture. We confess this effect of an electric spark, in accelerating the admixture of the gases, is quite new to us; and until we are better informed as to the manner in which the "mixing" spark is applied we must reserve judgment as to its probable efficacy. It is conceivable that a brush discharge might, by means of the so-called "electric wind," accelerate the mixture of two gases in which it took place; but we are not aware that anything analogous occurs around the electrode of an induction coil, unless the potential is very much greater than is usual in such coils when used for gas or oil engines. The phenomenon is at present enveloped in a certain amount of obscuring vapours which might with advantage be satisfactorily cleared up.

Cable Interruptions :—

	Date of Interruption.
Maranham-Para	Dec. 18, 1895.
Puerto Plata-Martinique	Dec. 19, 1895.

The Arc Lamp and the Meteor.—Some correspondents of *Nature* describe a brilliant meteor which was seen at Isleworth, Lewes, Dover and other places, on November 22nd. At Dover, it seems, the light emitted was said to have been "sufficiently brilliant to have thrown the electric light into shadow." The meteor, however, only lasted between one and two seconds; so the rivalry was short-lived.

Disastrous Hurricane.—The *Manchester Courier* of Saturday last publishes the following despatch from their correspondent at New York: "News of a disastrous hurricane along the Newfoundland coast is contained in despatches from St. John's. Among a considerable number of vessels that have been stranded is the French telegraph steamer "Pouyer Quertier," which it is feared will become a total loss.

Horseless Carriages.—The following interesting announcement appears this week in the columns of the *Engineer* :—

"Our readers will be interested to hear that the Memorial to the President of the Local Government Board which we prepared has now been presented to Mr. Chaplin. It bears upwards of 1,700 signatures, amongst which are the names of most of the principal firms of manufacturing engineers in the country, and many of the engineering societies, and county and other local officers. It was intended that a small deputation of leading firms should submit the Memorial, but Mr. Chaplin expressed himself to us as so entirely in sympathy with the movement that he did not think it necessary to trouble the deputation to attend."

Electric Motors in Furnace Work.—A new application of electric motors has been made in a German furnace plant. The Martin furnace at the Lauchhammer works, near Riesa, has to be charged eight times daily with about 13 tons of iron. This has hitherto been done by hand at a great expense of time and money, but with the new feeding apparatus one man can do in a tenth of the time the work of four men who have hitherto been necessary, and is not subjected to anything like the same temperature.

Expiry of a Sellon Secondary Battery Patent.—On Monday next, December 23rd, the Sellon patent, No. 5,631, for secondary battery plates, will expire. The patent claimed: "The construction of terminal plates, supports, retainers, or frames employed in secondary batteries of a material or materials not readily subjected to the destructive influence of oxidation in the manner and for the purposes herein described." Amongst the materials mentioned are carbon, asbestos, wood, *papier maché*, cellulose and platinum.

Effect of Magnetisation on Engine Governors.—Some time ago we mentioned the case of an engine governor which failed to perform its duty on account of magnetisation of its parts. The engine drove a dynamo, and it was thought that the stray field passing through the iron of the engine caused the trouble. It may be interesting to know that this trouble has been overcome by the ingenious expedient of fitting a non-magnetic cap of micanite between the eccentric and the hub of the wheel to which the eccentric is fastened, phosphor-bronze studs being used for fastening the parts together.

Philadelphia Tramway Strike.—A strike was entered upon last Tuesday afternoon at Philadelphia by some 4,500 drivers and conductors employed by the Union Traction Company, who suddenly abandoned their cars, owing to a difference in reference to wages. Within an hour, and practically without warning, 55 per cent. of the Company's cars were at a standstill; and,

Digitized by Google

as though the more effectually to prevent other men taking the vacant places, the strikers cut the trolley wires in all directions, and in this way largely blocked the tracks.

Another Pacific Cable.—In the United States Senate on Monday Senator Carter introduced a Bill authorising the Pacific Cable Company of New York to co-operate in the laying of a Pacific cable to Japan by way of Hawaii, the United States agreeing to pay an annual subsidy for 20 years at the rate of $25 per mile on a distance not exceeding 7,250 miles. The Bill also provides that United States Government messages shall be given the preference, that they shall be carried free for 20 years, and that in case of war the line shall be placed in possession of the United States.

The Brighton and Rottingdean Seashore Electric Railway.—The General Purposes Committee of the Brighton Town Council have resolved, on an application on behalf of the Brighton and Rottingdean Electric Tramroad Company, that the Company shall be released from the requirement that they shall provide sureties to join in the bond for £1,000 to be given by the Company for the removal of the poles about to be erected by them for carrying electric cables, and also that security for the removal of the railway in certain contingencies shall not be included in the bond.

Obituary.—We regret to announce the death, at Cape Town, on the 24th ult., of Mr. Philip Henry Bell, at the comparatively early age of 30. Mr. Bell was one of the first to be engaged in electric lighting by incandescent lamps, being connected with the Swan Company at Newcastle-on-Tyne almost from its commencement, and for many years held an important position with the Edison and Swan Company at Ponder's End. In the year 1894 he removed to Cape Town, where he has acted as manager of the electrical department for Messrs. George Findlay and Co. The news of his death from peritonitis, after a very short illness, has come as a great shock to a large circle of friends.

Development of Telephony in Austria.—The official statistics just published show the following figures for the year 1894. Figures printed in parentheses refer to 1893. The total number of telephones was 17,404 (14,941); of these the State controlled 9,295 (7,850), and a private company 8,109 (7,071). There were 121 (85) town systems with 8,365 (7,280) miles of conductor, 47 (40) interurban lines with 5,246 (4,155) miles of conductor, 112 (86) exchanges, 210 (177) public call offices, 8,723 (7,499) subscribers, and 223 (155) switchboards under State control. In private hands there was only the Vienna exchange, with 26,443 (26,170) miles of conductor, and one other exchange, 16 public call offices, 7,924 (6,902) subscribers, and 168 (152) switchboards.

Fatality at Cheltenham.—A fatal accident occurred on Monday last to a man at work in a sub-station of the Cheltenham electric supply system. The transformer station, 10ft. by 7ft. area, by 7ft. 6in. high, is below the footpath. The high-pressure mains in this chamber are at 2,000 volts. While working with other men, without insulating gloves, near the high-pressure switchboard, a man named John Pugh accidentally placed his arm, some inches above the wrist, in contact with a bare terminal on the high-pressure board. Death was almost, if not quite, instantaneous. Another workman, who was slightly in contact with Pugh at the time, received a severe but not injurious shock. The jury at the inquest have exonerated everyone from blame.

Damage by Lightning.—During the recent storm Devenish Round Tower, the most perfect of its kind in Ireland, was struck by lightning, and two of the stones fell from the summit, the caretaker on the island being a spectator of the occurrence. Some time ago much damage was done the old belfry by the lightning, and on the suggestion of Mr. Thomas Plunkett the Enniskillen Board of Guardians communicated with the Board of Works, and it was then understood that lightning conductors would be attached, certainly to the belfry, and probably to the tower. However, for so far nothing has been done. It is somewhat remarkable that two occurrences of this kind should have taken place within such a short period, seeing that for centuries these ancient buildings have stood unaffected by "time's effacing finger."

Swansea Electric Tramways.—The Swansea County Borough Council, at a meeting held last Tuesday, completed the negotiations for the purchase of the tramways, their conversion into electric tramways, and the supply to the lessee Company of electric energy at a rate depending upon the annual consumption. According to the agreement which has now been made it was settled that the Corporation was to pay £10,600 down to pay off debentures now held in the property of the Tramways Company; also to advance a sum of £21,600 to enable them to buy motor cars to work the tramways by electricity. That sum of money was to be repaid, firstly, by the interest, and, secondly, by a sinking charge over 30 years. The Corporation were to expend money in extending and doubling the lines, on which the Company were to pay interest equal to ½ per cent. more than what the Corporation paid for the loan. The Company were to take a minimum quantity of 400,000 units, at 2d. per unit; if 600,000 units, at 1¾d. per unit; and if 750,000, at 1½d. per unit. Any interest accruing during construction was to be added to the capital cost.

The "Low Pressure" Report.—The following extracts from some remarks in the *Builder* on the recommendations of the Board of Trade Committee on "low pressure" will be read with interest, coming as they do from a singularly well-informed journal, and representing therefore the opinion of the intelligent public:—"The report is certainly favourable to the electric lighting companies, and we think that the limit has been fixed at a higher value than the educated consumer will altogether appreciate. It is amusing to hear low-pressure electrical engineers declaring now that a pressure of 600 volts is quite safe; not so long ago they considered it deadly. It merely shows how easy it is to convince oneself when it is to one's interest to do so. From the consumers' point of view a 100-volt electric supply current is far preferable to a 200-volt supply. Anyone who has heard a fuse on a 200-volt circuit go off like a pistol shot needs little technical knowledge to understand that the danger of arcing across the terminals of cut-outs is far greater with the higher pressure. It depends now on the makers of electrical fittings and the wiremen to guard against this greatly-increased danger. . . . Electrical engineers are hastening on too quickly in their agitation for higher pressures. In time, when people know more about electric supply, it may be safe to use higher pressures, but at present it most decidedly is not. A few accidents due to this cause would do far more harm to the industry than the expense of a few tons more copper in their mains."

Steam Pipes and Elmore Copper.—We have been asked to publish the following Note, which Mr. J. T. Milton has appended to his "Remarks on Steam Pipes," an abstract of which appeared in our columns last week:—

"Since the reading of the above Paper Messrs. Elmore's Patent Copper Depositing Company (Limited) have communicated with me, expressing surprise and some doubt as to the accuracy of the figures given as representing the elastic limit of their material. Being anxious to get to the truth in this matter, I invited Messrs. Elmore to cut some additional strips from tubes, and to arrange to have a representative present at the tests. This invitation was promptly accepted, and Mr. Stanley Elmore attended with myself at the Central Technical College, when Prof. W. C. Unwin tested six specimen, two of them being annealed. The results are fully set out in the accompanying report. It will be seen that Messrs. Elmore's claim to an exceedingly high ratio of elastic limit to ultimate strength, in the copper supplied by them, is fully supported by the results of these tests."

Copy of Report made by Prof. W. C. Unwin on Specimens of Copper received from Mr. W. Elmore.

The Murphy-Pierce Sectional Conductor System of Electric Traction.—A new electrical railway system, invented by John M. Murphy and Albert F. Pierce, of Danbury, Conn., dispenses with the overhead wires and the conduit underneath the car. The surface only of the road is used, says the *Electrical Engineer* of New York, and the car takes the power from the section of rail directly beneath it. Between the rails on which the car runs is a third rail, laid in short sections, each section being perfectly insulated from every other section. The car, in passing, automatically engages the section of this third rail directly beneath it, and from it takes its power. This is done by one wheel of the car, which touches a push-pin, thus operating mechanism placed underneath the rail which in turn makes the connection with and charges the section of rail over which the car is passing. As the car moves forward and touches another pin, the section in the rear is cut out the same instant the one forward is charged. The main or feed wire insulated, is buried along the outside of the track. From this feed wire, insulated wires run to each section of the rail from which the car derives its power. These wires pass to the section through the mechanism by which the connection is both made and broken. The mechanism is simple, consisting of a lever, a pawl, a wheel, a shaft, and an electrical switch. All of this mechanism is encased in a box cast especially for it, water-tight as well as dust-proof. There is a fuse box between the wire and every section of rail, which makes it impossible to charge the rail up to the danger point. Any more than the required voltage burns the fuse and makes the rail dead. The charged rail is never exposed from underneath the car. All the mechanism used is cast in the foundry, making it comparatively inexpensive, and also possible to replace any part at a moment's notice. The electrical connection is made and broken by mechanical means. There is no magnetic switch device. An experimental section has been laid at Westport, Conn.

Fires and Electric Lighting.—Under the above alarming heading Major Flood-Page contributed a lengthy letter to Tuesday's *Times*, from which we take the following extracts:—

". . . Captain Simonds has been kind enough to furnish me with his reports for the years 1892, 1893, 1894, which show that, within the metropolitan area, fires have taken place, caused by candles, gas, lamps, and electricity, as follows:—

	1892.	1893.	1894.
Candles	175	235	157
Gas	265	284	284
Lamps	373	456	476
Electricity	1	5	3

These facts will surely allay any feeling of anxiety in the minds of users of electric light as to there being any practical danger from electric light properly installed in their houses. . . . I must, however, confess that I view with some alarm the efforts of some electrical engineers who are advocating an increase and in some instances actually increasing the pressure at which they deliver the current of electricity to 220 volts, while the ordinary current has been 100 to 110 volts. It is supposed by some that a difficulty has arisen in the manufacture of incandescent lamps to meet this demand. Permit me to say that the lamp presents the smallest difficulty in connection therewith. A far more serious question, and one which touches very closely upon fire insurance, is whether houses wired with fittings and switches manufactured for 100 volts can safely carry 220 volts. It stands to reason that before this change can be made every house must be inspected—switches, wiring, and fittings thoroughly tested and examined. I have no hesitation in expressing my own opinion that it is far better that we should, for many a day yet at any rate, be content with the useful safe pressure under which we have obtained the most satisfactory reports which these figures of the Metropolitan Fire Brigade show in connection with fire risks and electric light. I have said, and I repeat, that the lamp is probably the least difficult part of the whole question; but the question itself merits the most serious and earnest attention alike of those who supply and those who are using electric light for domestic purposes. Incidentally, I should like to remark that it is very doubtful whether the engineers who are advocating this increased pressure are entitled to do so, for the Electric Lighting Act, under which they are all working, provides that the undertaker shall not exercise any influence whatever as to the lamp which the customer is to use. The words of the Act are as follows:—'Electric Lighting Act, 1882. —The undertakers shall not be entitled to prescribe any special form of lamp or burner to be used by any company or person, or in any way control or interfere with the manner in which electricity supplied by them under this Act and any licence or special Act is used.' The primary sense of these words is probably that the undertakers shall not recommend the lamp of any particular maker; but I think it cannot be denied that they also bear the interpretation that the undertakers may not arbitrarily compel customers to change their lamps, which they must necessarily do if the current is supplied to them at 220 instead of 100 volts. In all seriousness, apart altogether from any legal question, this increase of voltage must exercise so important an influence upon that of safety that I trust the most careful consideration will be given by all users of electricity before they will submit to such increase, no matter what inducement may be held out by those who advise them to make the change. . . ."

The Boston "West End" Electric System.—The eighth annual report of the West End Street Railway Company, of Boston (U.S.A.), shows a handsome increase in both gross and net earnings. The gross earnings for the year ending September 30, 1895, were $7,746,170, compared with $6,823,879 the year before, an increase of $922,292. Operating expenses were $5,633,163, compared with $4,807,083 in 1894, an increase of $826,080. This reduced the net earnings to $2,113,007, an increase of $96,211 for the year. In his general remarks, which are more extended than those of last year, President Samuel Little outlines what has been accomplished by the West End in the past twelve months, and says:—"The act of the Legislature compelling the placing of electric wires underground in a certain defined district of the city, affected this Company to the extent of requiring all of its wires to be buried in the district named, except the trolley wires. The act of the Legislature required the Commissioner of Wires to designate the sections of this district upon which work should be accomplished each year, which section could not be more than one-fourth nor less than one-sixth of the whole district. The work already completed exceeds the requirements of the Commissioner for the first two years; 2·24 miles of conduits, containing 41·07 miles of duct, have been constructed, in which have been placed 23·31 miles of feeder cables and 13·93 miles of return feeders. The construction of the conduit and cable system takes the place of the overhead feeder wires. A contract has been made for electric heater equipments for the balance of the entire box car equipment of the road, which will all be installed and in operation the coming winter." The present equipment is as follows: Box cars, horse, 371; open cars, horse, 170; box cars, electric, 16-foot bodies, 92; box cars, electric, 20-foot bodies, 336; box cars, electric, 25-foot bodies, 445; open cars, electric, seven or eight benches, 582; open cars, electric, nine benches, 212; open cars, electric, ten benches, 47; mail cars, electric, 11; motor cars, electric, 2; horses, 857; electric motors, 2,108; snow ploughs, horse, 83; snow ploughs, electric, 115; snow sleds, 388; miscellaneous vehicles, 482.

Contemporary Electrical Science.—In the December number of the *Philosophical Magazine*, Prof. Holman, of the Massachusetts Institute of Technology, corrects the statement made five years ago by Messrs. Ayrton, Mather and Sumpner, that in the coil of a sensitive (Thomson) galvanometer the current in a portion of the central turns affects the needle in opposition to the remaining major portion of the turns; so that this portion should be left out or connected in reverse direction. The space containing these turns was pointed out as being nearly "an oblate spheroid with a polar axis about 0·72 of its equatorial diameter, the latter being, of course, slightly larger than the length of the needle." As a matter of fact, this volume is about one-quarter to one-eighth of that indicated, and the error arose from the fallacy of considering the deflective moment upon the needle as due to the field at the poles merely, and not over the remainder of the needle. The space inside the null surface is approximately a sphere whose diameter is about half the length of the needle. Hence it is practically useless to wind turns within a distance of one-quarter of the needle from the centre. To increase sensitiveness, the needle must be made as short as is consistent with torsion of suspension.——In the same number, Prof. J. J. Thomson has a very interesting Paper on the relation between the atom and the charge of electricity carried by it, which will amply repay a careful perusal. In the electrolysis of solutions, the hydrogen ion always carries a positive charge, the chlorine ion a negative one. But in the electrolysis of gases, both of these atoms are capable of carrying either positive or negative charges. The author elucidates these properties by reference to gyrostatic and hydro-dynamical analogies, and propounds a new electrical theory of chemical combination. At no stage of this process are any atoms set free, and this has been proved by the absence of conductivity. An electrified plate when immersed in a gas by which it is attacked does not lose its charge.

NOTES ON AN INVESTIGATION OF THE ALTERNATING-CURRENT ARC.

BY J. A. FLEMING, D.SC., F.R.S., AND J. E. PETAVEL.

During the last six months investigations have been carried on by us in the electrical laboratory of University College, London, with the assistance of some of the senior students, which form part of an analytical study of the alternating-current arc as yet not quite complete. Results, however, have been obtained which it will probably be of interest to the readers of *The Electrician* to put on record, pending a complete publication of the details of the investigation. A short communication was sent by one of us last year to the pages of a contemporary journal,* containing an account of preliminary experiments carried out some time ago, in which a comparison was made between an alternating-current and a continuous-current arc in respect of the total spherical candle-power yielded for the same expenditure of power in the two arcs. These experiments have since been continued and repeated with greater care. They form the first portion of the above-mentioned investigation. The general description of the arrangements employed in their conduct was as follows :—

Two arc lamps were selected of well-known types—one of them suitable for working with continuous current and the other with alternating current, the lamps being chosen with a view to good regulation and steady working over wide limits of power consumption. The particular types of lamp employed were of no consequence except in so far as they were lamps capable of being used with alternating and continuous currents throughout the limits required.

The first portion of the experimental work consisted in the construction of an inspectional reflecting wattmeter, intended to enable the observers to measure and to regulate with great accuracy the power taken up in the arc itself, neglecting altogether the power absorbed in the mechanism of the arc lamp. Briefly speaking, this wattmeter consisted, as usual, of a fixed coil, which was the current coil of the instrument, and through which the current of the arc passed, and a movable coil hung by a bifilar suspension, the two suspending wires being exceedingly fine silver wires. In series with the suspended coil was a non-inductive resistance, capable of being varied in magnitude within certain limits. The suspended coil had affixed to it a plane mirror, and an image of a wire illuminated by an auxiliary arc lamp was thrown by it on to a fixed scale. The suspended coil consisted of 33 turns of wire, and the fixed coil of 10 turns of thicker wire. The non-inductive resistance, in series with the suspended coil, had a resistance of 1,200 ohms, the resistance of the shunt coil of the wattmeter being 3·67 ohms, and that of the fixed coil 0·01 ohm. The wattmeter was fixed firmly to a wall, and the scale carried at a fixed distance opposite to it. The wattmeter was calibrated by means of continuous currents and by means of an interpellation curve the power reckoned in watts passing through the wattmeter could be read off from the position of the image of the wire thrown upon the fixed scale. The terminals of the fine wire coil were connected to the arc carbons. In all the experiments the wattmeter readings were subsequently reduced so as to give the true power taken up in the arc, neglecting the power required to actuate the arc lamp mechanism and the power taken up in the voltmeter and wattmeter itself.

In addition to the wattmeter measurements, the current through the arc, as well as the potential difference between the carbons, was taken by properly corrected instruments, and the length of the arc was also measured at the same time by projecting its image upon a screen. The photometric measurements were made with a Sugg's star disc photometer, the light from the arc lamp being compared by this means with that of an incandescent lamp, which was worked at a sufficient voltage to bring it up to about 2½ watts per candle, the incandescent lamp being compared at frequent intervals with a primary standard incandescent lamp.

The colour difference in the two lights to be compared gives rise to a certain difficulty in making the photometric measurements, which can only be overcome by an observer whose eye is sufficiently well trained to detect minute differences of brightness and neglect the existing colour difference of the two images in the photometer. It was found that by focussing the eye for a point rather nearer to the eye than the images of the photometric disc, the colour difference between the two images became less distracting, and in this manner the observations that were made are all taken in terms of a white-light standard, no measurements made in terms of red or green light having any practical value. The experiments consisted in taking a series of observations of the photometric intensity of the arc in different angular directions to the horizontal plane through the arc in the usual manner, the power supplied to the arc being kept perfectly constant by a regulating carbon resistance in series with the arc. The use of the bifilar reflecting wattmeter enabled this to be done with the greatest ease and accuracy. A complete series of observations was taken with the continuous-current arc when supplied with power of from 200 to 600 watts. For each complete set of observations the wattage in the arc was kept perfectly constant, and from the photometric observations the ordinary illumination curve of the arc could be plotted out, and the mean spherical candle-power calculated in the usual way by means of Rousseau's diagram. In the case of the alternating-current arc, owing to the circumstance that there is a slow periodic rotation or change of place of the arc, quite independent of the fact that the current or the wattage in the arc is maintained perfectly constant, the photometric measurements become particularly troublesome. In this case it was necessary to take a series of photometric observations rapidly in different azimuths for each particular inclination angle, and to take the mean of these observations. Carrying out this process, a series of illumination curves was obtained for the continuous and the alternating-current arc, which had the usual characteristic form. In both cases these experiments and measurements of the mean spherical candle-power were repeated for different expenditures of power in the arc varying from 200 to 600 watts. The alternating-current experiments were made at two frequencies—viz., 50 ∿ and 83·3 ∿. The carbons used in the case of the alternating-current experiments were both 15mm. cored carbons of the best quality, and in the case of the continuous-current arc experiments two sets of observations were made, one with both carbons cored and 15mm. in diameter, the other set with the positive or upper carbon cored and 15mm. in diameter, and the lower or negative carbon solid and 9mm. in diameter. When all the necessary reductions of the hundreds of observations were made by the integration of the illumination curves to give the mean spherical candle-power, and the reduction of the wattmeter scale readings to give the true power in watts expended in the arc itself, apart from anything taken up in the mechanism or instruments, the results were embodied in a series of curves as shown in Fig. 1, in which the horizontal distances represent the power in watts taken up in the arc, and the vertical ordinates the mean spherical candle-power. The four curves there shown show the variation of mean spherical candle-power for the particular carbons used for the various powers employed in the case of

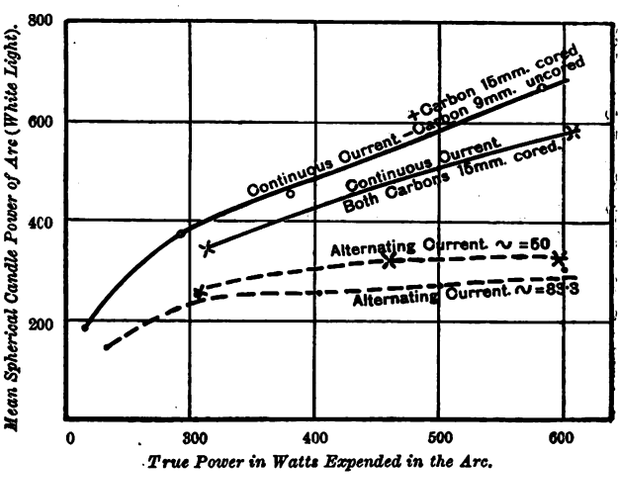

FIG. 1.

* In these observations the arc was hissing during the whole of the time.

In reading the above Table it must be noted that it was the power, measured in watts, taken up in the arc which was kept constant. The current and difference of potential of the carbons were allowed to take care of themselves. The current and volts were approximately constant, and had the mean values given in the Table, but the product of these mean values does not quite agree with the true mean power measured in watts taken up in the arc.

both arcs, the details of the observations being given in the table above.

The general result of the above described experiments therefore confirms the conclusions reached by one of us in 1894, and which indicated that for a given amount of power expended in the arc under the conditions under which these experiments were carried out, the mean spherical candle-power for continuous current was nearly double that for the alternating current. It is now well understood from the experiments of Messrs. Wedding and Roessler and others that the mean

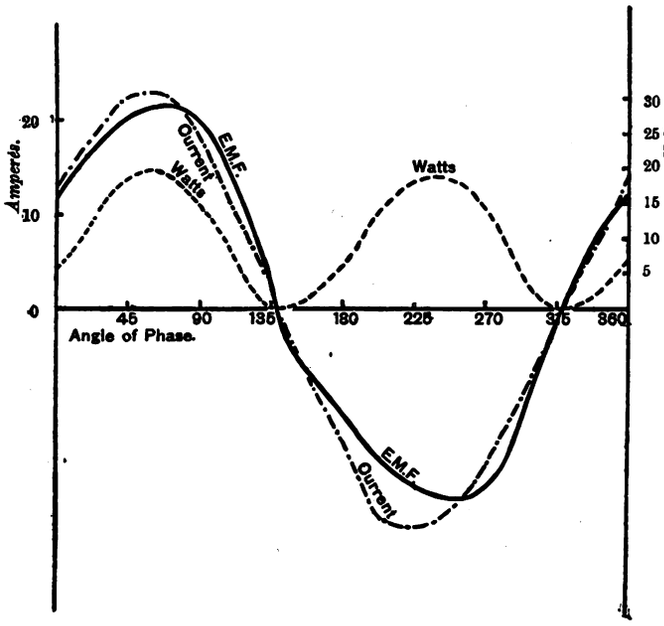

FIG. 2.—The curve marked E.M.F. is the curve of variation of potential difference of the carbon poles for an alternating current arc. The dotted curves are curves of current and power. ∿ =83·3; amperes=15; volts=18; watts=260.

spherical candle-power in the case of the alternating-current arc for a given amount of power expended in the arc, depends, amongst other things, upon the form of the carbon potential difference curve. A set of current and electromotive-force curves was in all cases taken for the alternating-current arcs employed by us, for the various powers of from 200 to 600 watts, and for both frequencies of 83·3 ∿ and 50 ∿, which curves showed the form of the variation of the current and electromotive force. One set of these curves is shown in Fig. 2, as an illustration of the kind of curve found.

The above described experiments do not, of course, by any means exhaust the subject. The question whether continuous-current arcs *per se* are more efficient than alternating-current arcs in regard to mean spherical candle-power produced per watt is a large question to consider, and perhaps cannot be answered in a general sense, but it is capable of being settled for any particular instances which occur in practice. It is for this reason that we selected the two typical cases of an alternating-current arc worked with 15mm. cored carbons worked at frequencies 83·3 ∿ and 50 ∿, and compared it with a continuous-current arc worked with 15mm. and 9mm. carbons as commonly employed. The experiments, of course, do not settle whether any particular form of alternating-current arc can be produced which shall give the same mean spherical candle-power for a given expenditure of power as a continuous-current arc with the same carbons, and such a question has, perhaps, too purely an academic interest to make it worth while to spend time upon it.

These experiments amply justify generally the opinion which has been held as to the relative inefficiency of alternating-current arcs in mean spherical candle-power, apart from any question as to differences in the distribution of the light, and show the correctness of the opinion which dictates the employment of continuous current or rectified alternating current for public arc lighting purposes.

The second part of the investigation was concerned with an analytical examination of the periodic variation of light coming from various parts of an alternating-current arc. For this purpose an alternating-current arc was formed with currents of frequencies of about 83 ∿, 50 ∿, and 25 ∿. The synchronising motor curve-tracer described by one of us in *The Electrician* for 1895, Vol. XXXIV., p. 460, was employed in the following manner to examine these arcs:—

A disc of aluminium of about 27cm. in diameter had four small radial slits cut in it 90deg. apart, the length of each slit being 4·5cm., and mean width about 0·5cm.; this disc was

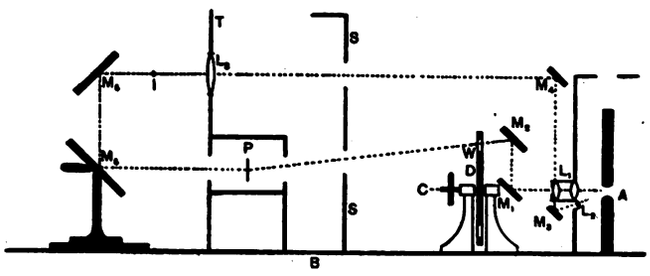

FIG. 3.

attached to the shaft of the synchronising motor, and driven from the same circuit which supplied current for the alternating arc. The disc was therefore driven synchronously with the arc. The motor has eight field poles, so that the disc turned through 90° in each complete period of the alternating current. In Fig. 3 a diagram is shown representing in outline the arrangement for obtaining the variation of illuminating power of any part of the arc during the complete phase. Owing to the slow variation in the total illumination of the arc, it is impossible to photometer the instantaneous value of the light of the arc against any fixed-light standard with any chance of securing accurate results; but the difficulty was overcome by using the *arc itself* as a standard, and photometering the mean value of the light emitted from any part of the arc against the instantaneous value of the light from the same part of the arc, taken at any instant during the phase. In Fig. 3, A represents the alternating-current arc; the light from this arc passed through a lens, L_1, in a horizontal direction, and fell upon a mirror, M_1, placed at an angle of 45deg., and capable of being rotated round a horizontal axis in line with the axis of the revolving disc. D represents a section of the revolving

Digitized by Google

disc, W being one of the radial slits. The motor shaft was attached to the disc axis C. The ray, reflected from M, was then reflected upwards to a mirror, M_2, and passed through one of the windows W in the revolving disc, finally falling upon the photometric disc P. The lens L_1 thus formed an image of the arc on the disc P. Another ray, proceeding from the arc in the same horizontal plane, but in a direction slightly inclined to the first ray, passed through a lens, L_2, and fell upon another mirror, M_3, which, in the diagram, for diagrammatic purposes, is represented as below the lens L_1, although really its centre is on the same horizontal plane with it. This second ray was reflected up to the mirror M_4, passed through an aperture in a screen, S, and fell upon a lens, L_3, the lens L_2 forming a rather blurred image of the arc upon the lens L_3, so that by slightly moving the mirror M_4 any part of the image of the arc or the incandescent carbons could be made to cover the lens L_3. After passing through the lens L_3 the beam was brought to a focus at I, and then fell upon two mirrors M_5 and M_6, fixed together on a vertical stand at angles of 45deg. so as to reverse the direction of the beam and cause it to fall upon the other side of the photometric disc P. The lens L_3 formed a real image of any required part of the arc at some point I between L_3 and M_5. By moving the two mirrors M_5 and M_6 together to or from the photometric disc, the length of the path from the image I to the photometric disc could be varied, and therefore the light falling upon the star disc of the photometer which came along the path $M_4 M_5 M_6$, and which was selected from any part of the arc or the incandescent carbons, could be varied in intensity. When the disc D is set in rotation the light passes intermittently through the windows W, and the lens L_1 forms a sharp image on the disc P, which is apparently continuous, but really interrupted, and any part of this image could be made to fall on the disc P by moving slightly the mirror M_2. The right-hand side of the photometric disc is illuminated therefore by an intermittent stream of light which is always selected in the same phase when considered as belonging to a periodically varying illuminating beam, in consequence of the fact that the rotation of the disc is synchronous with the period of the arc. On the other hand, the light which falls on the left-hand side of the disc is a uniformly illuminating beam coming from the same part of the arc, the intensity of which at the point P depends upon the square of the length of the path I M_5 M_6 P. By moving the mirrors M_5 M_6 to or from the disc P, a balance could be obtained between the right and left-hand illuminations, and therefore the instantaneous value of the light coming from any part of the arc or carbons could be photometered against the mean value of the light coming from the same part of the arc or carbons, the length of the arc and the current through the arc being kept perfectly constant through the experiment. At the same time the motor alternator driving the revolving disc was employed to make the intermittent contact by which, in the usual manner, the current and electromotive force curves of the arc were delineated, and the diagram Fig. 4 shows a complete set of observations giving the current through the arc, the potential difference between the carbons, the power expended in the arc, and the variation of the light in the centre of the true arc, excluding any light coming from the incandescent carbons. The firm line curve in Fig. 4 therefore represents, by its ordinates, the periodic variation of the light coming from the purple arc discharge lying in between the carbons, but does not include any light coming from the carbons themselves. The light is selected for measurement at particular instants during the complete phase, as follows:—The image of the arc formed by the light which comes through the windows of the revolving disc is received on the disc P, and we have an image formed there which represents the state of the alternating-current arc in some particular phase, depending upon the angular position of the axis which joins together the mirrors M_1 and M_2. The mirrors M_1 and M_2 are fixed upon a radial arm, which connects them together, and which is capable of being moved round in a vertical plane, so that the line $M_1 M_2$ revolves round a centre, M_1, and is capable of being placed in any angular position within certain limits with respect to the vertical line through M_1. By rocking round this arm the light which passes through the window W is that which is taken from the arc at a particular instant during its complete periodic change. Under these circumstances the image that is seen formed upon the screen can be made to exhibit any of the conditions which exist in the arc during the complete period by moving the rocking arm carrying the mirrors M_1 and M_2 through a certain angle. It is thus found that the blue or purple light forming the true arc in between the carbons undergoes a periodic variation in intensity, completely vanishing at a certain instant during the phase, but at the same time there is outside this true arc a dim halo of golden light which is persistent, and it is on account of this persistent aureole of faint light that the ordinates of the firm line curve in Fig. 4, which represent the variation of light in the true arc, never

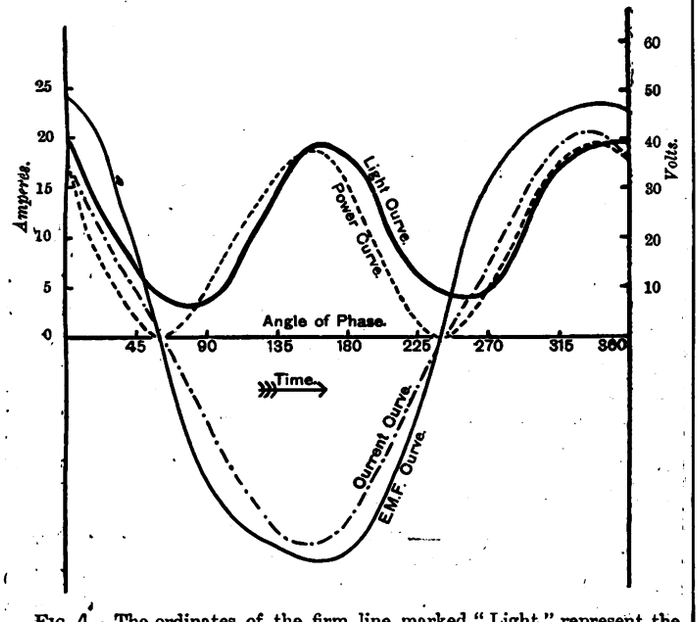

FIG. 4.—The ordinates of the firm line marked "Light" represent the periodic variation of illuminating power of the centre of the *true arc* of an alternating-current arc. The other curves marked E.M.F., current and power represent the variation of potential difference of the carbons, current and power in the arc. Carbons, 15mm. cored; $\sim$ = 83·3; amperes = 14; volts = 39; length of arc, 0·55cm.; volts at alternator terminals = 104.

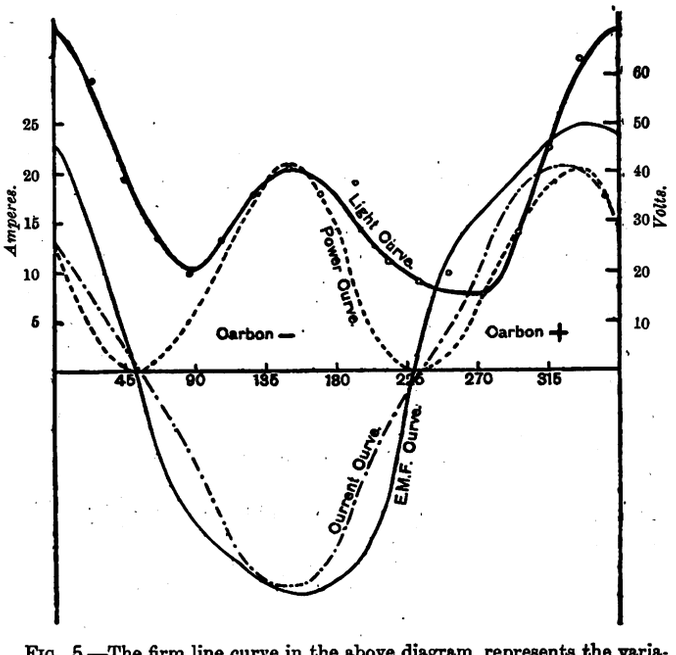

FIG. 5.—The firm line curve in the above diagram represents the variation in illuminating power of the *crater* of the lower carbon during one complete phase of an alternating-current arc. Carbons, 15mm. cored; $\sim$ = 83·3; amperes = 14; volts = 36; length of arc, 0·42cm.; volts at alternator terminals = 98.

Digitized by Google

become zero, but there is always an outstanding constant amount of light. In order to select as far as possible merely the blue or purple-coloured light from the true arc, irrespective of any admixture of white light coming from the aureole, a blue gelatine transparent screen was employed to select a certain group of rays. By shifting the position of the mirrors M_2 and M_4 slightly, it was possible to measure the periodic variation of light coming from any part of the incandescent carbons. The diagram in Fig. 5 represents the periodic variation of light coming from the centre of the crater of the lower carbon, the other curves of the same diagram representing the variation of current through the arc, potential difference between the carbons, and power expended in the arc. It must be noted that the scale to which the light curve in Fig. 5 is drawn is very different from that of the light curve in Fig. 4, as the crater is, of course, far more brilliant than the true arc. The interesting point to notice is that during the time when the lower carbon is negative, the maximum light emitted from the centre of the crater of the lower carbon does not reach such a maximum value as it does when the same carbon is positive. For a frequency of 83 it is not much more than one-half as great—that is to say, the brilliancy of the crater on the carbon undergoes a periodic variation, but at the instant when the carbon is negative and when the maximum power is being expended in the arc, the brilliancy of that part of the carbon is not much more than one-half that which it is when the same carbon is positive and receiving its maximum power expenditure. The lower the frequency, the greater this difference. It is easy to distinguish the part of the period during which the lower carbon is negative from that in which it is positive by holding a magnet at the back of the arc and noting which way it causes the image of the arc to be deflected, which image is formed by the lens L_1.

It is evident from the curves in Fig. 5 that there is a certain lag in the curve representing the variation of light from the carbons behind the curve representing the power; in other words, the light lingers on a little after the power has fallen to zero. It will also be noticed there is a very slight difference of phase between the current and electromotive force, which is also found in all the other curves taken with the alternating-current arc.

These investigations are as yet not quite complete, but we propose later on to publish a full account of them. The observations have necessitated an enormous number of photometric and electrical measurements, and we have in this work been very efficiently aided by Messrs. L. Birks, W. H. Grimsdale, A. M. Hanbury, E. N. Griffiths and others who have taken part in the research, and to whom our thanks are due.

SPEED-VOLTAGE CURVES.

BY J. ALFRED GRIFFITHS, B.SC., WH. SCH., &c.

The predetermination of the relations of speed and potential for a self-exciting dynamo is of direct importance when the prime mover is uncontrollable and subject to irregular fluctuations of speed of considerable extent, as in the cases of wind-power storage and of train lighting from the axles of the carriages; it is also useful in the case of constant current regulated by varying the speed, in the arrangement of compound winding, and in the design of low-speed dynamos.

When a dynamo is started with the speed slowly increasing in small steps it is noticed that at first the potential is imperceptible, or very slight, and that the dynamic building of the magnetic field does not commence until a certain critical speed is reached, at which very often a slight increase of speed causes a decided jump in potential, which afterwards increases steadily with each increment of speed. The reason for this absence of dynamic increment at low speeds is by no means obvious from text-books and published papers, attention being usually concentrated on the action of the dynamo under an ideal constant speed that is but approximately realised in practice. The following method of investigation will be useful to students, and may possibly be interesting to experienced electricians.

In the first instance, consider a continuous-current bi-polar dynamo without any external load, so that the distinctions of series, shunt, or compound-winding do not complicate the question, and in which both armature reactions and permanent magnetism are so small as to be negligible.

Let the curve O A B represent the magnetic properties under separate excitation of the dynamo carcase, including its armature *at rest* and the air gaps; the abscissæ measuring the total ampere-turns in the field coils and the ordinates the average magnetic density in the air gaps (after allowing for leakage) in C.G.S. lines per square centimetre of *effective* gap or pole area. The full line represents the induction as the ampere-turns are slowly increased, and the dotted line the induction with diminishing excitation. On the same diagram, O C (tangent, or nearly so, at O to O A B) will represent the relation between the magnetic density in the gap space and that portion of the ampere-turns required to overcome the reluctance of the air gaps alone.

The scales used in the diagram will suit a dynamo having the following dimensions:—

A = effective pole area = 1,600 sq. cm.;
B = C.G.S. lines per square centimetre in the gap;
$2l$ = total length of double gap = 3·0cm.;
C = total conductors round armature = 80;
r_a = armature resistance from brush to brush = 0·01 ohm;
E = total electromotive force in the armature;
Z = number of coils in shunt winding = 3,260;
r_s = total resistance of shunt coils = 16·93 ohms;
S = number of series coils;
r_s = resistance of series coils;
R = external resistance of working circuit;
i_a, i_z, i_s = currents in the several circuits;
n = speed in revolutions per second.

The equation to the gap-line O C will then be:—

$$\text{A.T.'s} = B \times 2l \times \frac{10}{4\pi} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$= B \times 2{\cdot}3874 \text{ for the particular dimensions.}$$

Next, consider the density in the gap, B, to be independently varied, while the armature is maintained in uniform motion. Then for each value given to B a potential will be induced in the armature capable of generating a current in the field coils, and since the speed and resistance are constants, the ampere-turns of such current will be directly proportional to the density B, and the relation may be expressed by a straight line through O, or by the equation

$$\text{A.T.'s} = \frac{E}{r_a + r_s} \times Z = \frac{B \times A \times C \times n \times Z}{10^8 \times (r_a + r_s)} \quad . \quad . \quad . \quad (2)$$

Let O A be such a line (which may be named a *speed line*) cutting the ascending magnetic curve in the point A, at which 20,840 ampere-turns are produced by the armature revolving in a field of density $B = 7{,}050$ at a speed of 12 revolutions per second; and also (on the magnetic curve) a field of $B = 7{,}050$ is generated in the gap by 20,840 ampere-turns acting in the complete magnetic circuit. Obviously there is equilibrium at A, and the dynamo will excite itself at that stage.

The same squared paper may be used for the speed-voltage diagram, measuring revolutions along Y Q and volts along X Q, the origin being still at O, by choosing suitable units. Through the point D, where the speed line of the magnetic diagram cuts the corresponding speed ordinate (in the example, for 12 revolutions per second), draw the dotted line C D E parallel to O X. This line may be called the *scale of speeds* for the particular winding of armature and field under consideration, for if a line is drawn to O from any point on the speed line, it will represent the relation of the density of field to the ampere-turns generated by the armature at the speed indicated by that point on the speed scale. If on the squared paper, p ampere-turns measure q revolutions, then from equation (2)

$$B_n = \frac{p}{q} \times \frac{10^8 (r_a + r_s)}{A \times C \times Z} \quad . \quad . \quad . \quad . \quad (3)$$

which fixes the height of the speed scale on the scale of magnetic density.

None of these speed lines O F, O G between O Y and O C cut the ascending magnetic curve O A B, showing that at speeds

Digitized by Google

lower than that represented by O C (the gap-line) the ampere-turns generated by the armature will not excite the necessary field for self-excitation. On the other hand, if the armature be moving at any constant speed greater than O C, and the circuit (previously supposed open) be closed, then, if there is ever so little residual magnetism or other cause which will start any faint current, the ampere-turns of that current will be competent to excite a denser field than is necessary to induce the first faint current; thus the current and field will be mutually strengthened until the point is reached where the speed line and ascending magnetic curve intersect, where there will be equilibrium and the process will stop. For example, suppose the speed to be 12 revolutions per second (speed line O D) and the initial field be but 60 C.G.S. lines due to permanent magnetism; the potential in the armature will generate only 177 ampere-turns, yet these 177 ampere-turns will excite a dynamo field of about 70 C.G.S. lines, the potential from which is competent to generate 208 ampere-turns. Thus the current and field will increase until at about 4,700 C.G.S. lines the surplus ampere-turns will be about 2,000. From this point as the current increases the surplus will diminish, until the intersection of the rising magnetic curve and the speed line is reached when the surplus vanishes and a stable field is established.

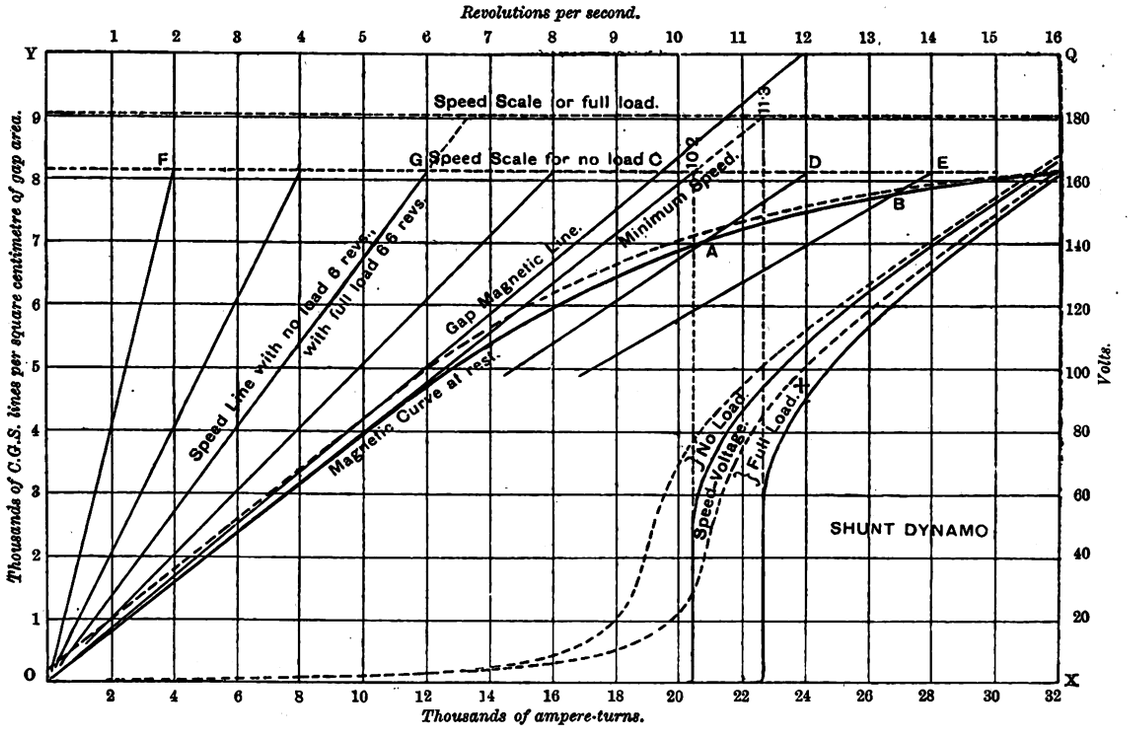
but as this is impossible, the curve may be determined graphically for any given magnetic curve. By drawing a sufficient number of speed lines, and scaling the value of **B** at the intersections with the magnetic curve, the corresponding armature potential may be calculated by the equation

$$E = \mathbf{B} \times n \times \frac{A \times C}{10^8}; \quad . \quad . \quad . \quad . \quad . \quad (5)$$

for the example in the diagram

$$\frac{A \times C}{10^8} = \frac{1{,}600 \times 80}{10^8} = 0{\cdot}00128.$$

The rising and falling branches of the magnetic curve may be separately treated as in the diagram (the measurements and calculations for which are tabulated in the appendix) or a mean magnetic curve may be used for practical convenience. When the speed is decreasing the speed-voltage curve lies above that for rising magnetism, and the excitation does not stop suddenly when that value of n is reached at which self-excitation commenced, but continues to zero speed with the low but perceptible value shown in the dotted voltage curve. The greater the residual magnetism the greater will be the space between the two curves. This property greatly helps the stability of the potential with small variations of speed,



Evidently, the minimum speed below which the self-excitation will not begin is that for which the speed line through O is coincident with the line O C, representing on the magnetic diagram the ampere-turns required for the gap-reluctance. Since only linear functions are involved, this minimum speed is easily expressed in terms of the dimensions of the dynamo by equating the ampere-turns from equations (1) and (2) thus:

$$\mathbf{B} \times 2l \times \frac{10}{4\pi} = \frac{\mathbf{B} \times A \times C \times n_0 \times Z}{10^8 \times (r_a + r_s)},$$

whence

$$n_0 = \frac{10^8}{C} \times \left(\frac{2l}{A} \times \frac{10}{4\pi}\right) \times \frac{r_a + r_s}{Z}. \quad . \quad . \quad . \quad (4)$$

Usually r_a is quite negligible compared with r_s, and then

$$n_0 \text{ varies as } \frac{\text{gap reluctance} \times \text{resistance of one field coil}}{\text{total armature conductors}}.$$

With some open-coil armatures (such as the Siemens shuttle) the minimum speed will be half of the above value (4), and with parallel-connected multipolars C will be the number of armature conductors for each pair of poles.

If the magnetic function could be algebraically expressed, the next step would be to write down the equation for the whole speed-voltage, and to trace its curve shape analytically; for a small drop in speed is not immediately followed by a drop of potential to the value for the lower speed on the rising curve, and the induction may not change until the speed has fallen to a value corresponding to that potential on the falling curve—*i.e.*, through a change of speed measured by the horizontal distance between the ordinates for the two branches of the speed-voltage curve at the one potential.

When the permeability at low stages is so nearly uniform that the magnetic curve near the origin is practically straight, then the induction through this stage is a linear function which may be added to the expression for the air-gap, and the minimum speed will be that for which the speed line coincides with the straight part of the magnetic curve. If the uniform permeability is known the minimum speed will be

$$n_0 = \frac{10^8}{C} \times \left(\frac{2l + m}{A} \times \frac{10}{4\pi}\right) \times \frac{r_a + r_s}{Z}, \quad . \quad . \quad . \quad (6)$$

m being the length of air-gap that has the same reluctance as the iron carcase at low stages of magnetisation. Usually, however, this special minimum speed is most easily obtained graphically by drawing a tangent, as in the diagram, at O H.

Having determined a speed voltage curve as in the diagram for any particular height of speed scale (say $\mathbf{B}_a = 8{,}130$), the

Digitized by Google

curve for any other position of speed scale (say $B_n = 9{,}020$), due to different winding or to the addition of an external load, may be proportionately computed and plotted. If a speed line be drawn through any particular value of B on the magnetic curve, then the speed represented thereby will be increased in proportion to the height of the new speed scale, and the potential in proportion to the same alteration of height (and to the alterations of winding, if any). This may be done graphically or numerically. By the graphic method (when the winding is unaltered) take any corresponding points on the magnetic and potential curves; through the point on the magnetic curve draw a speed line, and from its intersection with the new speed scale drop the ordinate perpendicular to OX; through the point on the old potential curve draw a vector from the origin to cut the new ordinate in the desired point on the new potential curve. Numerically a slide rule may be set up for the ratio of the speed scale heights, and the new co-ordinates written down in tabular form, as in the appendix, and plotted.

When work is done through an external circuit, either with series or shunt connections, a greater speed is required for any particular potential than with no load. This is due to the reduction of the ampere-turns both from the alterations of the electrical circuit and by the armature disturbances. Some assumption must be made as to the nature of these disturbances, of which the most important is the demagnetising of the field by the back ampere-turns of the armature. When the external circuit is constant and only the speed varies, the variation of brush lead for sparklessness will not largely affect the result, and the back ampere-turns may be taken simply as proportional to the armature current, and expressed by $i_a \times b\,C$, b being the ratio of half the conductors in the demagnetising belt to the total number.*

Taking this approximate expression for the main armature reaction, and neglecting minor disturbances, the three main formulæ become, for a series dynamo with external circuit of resistance R :—

$$\text{A.T.'s} = i_a \times S - i_a \times b\,C = \frac{E \times (S - b\,C)}{r_a + r_s + R}, \quad . \quad . \quad (7)$$

$$B_n = \frac{p}{q} \times \frac{10^8}{A \times C} \times \frac{r_a + r_s + R}{S - b\,C}, \quad . \quad . \quad . \quad . \quad (8)$$

$$n_0 = \frac{10^8}{C} \times \left(\frac{2\,l}{A} \times \frac{10}{4\pi}\right) \times \frac{r_a + r_s + R}{S - b\,C}; \quad . \quad . \quad (9)$$

} Series

and for a shunt connection,

$$\text{A.T.'s} = i_s \times Z - i_a \times b\,C = E \times \frac{R\,Z - (r_s + R) \times b\,C}{r_a r_s + r_a R + r_s R}, \quad (10)$$

$$B_n = \frac{p}{q} \times \frac{10^8}{A \times C} \times \frac{r_a r_s + r_a R + r_s R}{R\,Z - b\,C \times (r_s + R)}$$

$$= \frac{p}{q} \times \frac{10^8}{A \times C} \times \frac{\frac{r_a r_s}{R} + r_a + r_s}{Z - b\,C \times \left(1 + \frac{r_s}{R}\right)}, \quad (11)$$

$$n_0 = \frac{10^8}{C} \times \left(\frac{2\,l}{A} \times \frac{10}{4\pi}\right) \times \frac{\frac{r_a r_s}{R} + r_a + r_s}{Z - b\,C \times \left(1 + \frac{r_s}{R}\right)}. \quad . \quad (12)$$

} Shunt.

The lowest position of the speed scale is when B_n is a minimum, which occurs with series connections when $R = 0$ and the current has a maximum value, and with shunt connections when R is infinite and the external current has vanished. This limiting value of B_n is in both cases the same, Z and S being then interchangeable,

$$\text{Minimum } B_n = \frac{p}{q} \times \frac{10^8}{A \times C} \times \frac{r_a + r_s}{Z - b\,C}. \quad . \quad . \quad (13)$$

With compound winding the series coils may be used either to oppose the demagnetising action of the armature and circuit resistances, resulting in an increased potential at any given speed, or they may be reversed; the former method being useful to obtain constant potential at approximately constant speed, and the latter to obtain a drooping external characteristic to prevent excessive current at high speeds when the prime mover is uncontrollable as to speed, as in the cases of wind power and railway carriage axles. The three formulæ for compound winding are :—

$$\text{A.T.'s} = i_s \times Z + i_s \times S - i_a \times b\,C$$

$$= E \times \frac{R\,Z + r_s\,S - b\,C \times (R + r_s)}{r_a r_s + r_a R + r_s R}, \quad . \quad . \quad . \quad . \quad (14)$$

$$B_n = \frac{p}{q} \times \frac{10^8}{A\,C} \times \frac{r_a r_s + r_a R + r_s R}{R\,Z + r_s S - b\,C\,(R + r_s)}, \quad . \quad . \quad (15)$$

$$n_0 = \frac{10^8}{C} \times \left(\frac{2\,l}{A} \times \frac{10}{4\pi}\right) \times \frac{r_a r_z + r_a R + r_z R}{R\,Z + r_z S - b\,C\,(R + r_z)}. \quad (16)$$

} Compound.

In these R includes r_s, and the sign of S is positive or negative according as the series coils help or oppose the shunt coils.

In order that the two windings shall exactly compensate, a value of S must be chosen, which, if possible, will bring the position of the speed scale to the same height with external resistance = R as the minimum height. By equating the values of B_n from equations (13) and (15),

$$\frac{r_a r + r_a R + r R}{R\,Z + r\,S - b\,C\,(R + r_z)} = \frac{r_a + r_z}{Z - b\,C},$$

hence

$$S = \frac{r_a\,Z + r_z\,b\,C}{r_a + r_z}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (17)$$

The elimination of R from this value of S indicates that if the brush lead is not altered then the total armature potential will be constant at any particular speed for all external loads, when that number of series coils assists the shunt. The first part, $\frac{r_a Z}{r_a + r_s}$, represents the coils needed to compensate the drop in potential due to armature resistance, and the latter part, $\frac{r_s\,b\,C}{r_a + r_s}$, the coils needed in respect of the belt of back ampere-turns supposed to be of constant width. If further hypotheses are made concerning the variations of b, or of other disturbances of potential, the expression for S will be extended, but R may not be eliminated, as is found practically when compounding for constant external potential. But since R cannot be eliminated from the fundamental relation of total and external potential it cannot be expected that perfect compounding for external potential should follow its elimination from the total potential.

With certain chord-wound armatures, the demagnetising is insensible, and equation (17) becomes

$$\frac{S}{Z} = \frac{r_a}{r_a + r_s}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (18)$$

In the diagram, the speed-voltage curve for no-load is plotted for a value of $B_n = 8{,}130$ from equation (13), assuming

bC to have a constant value $\frac{C}{17{\cdot}8}$, and for full load a current of 320 amperes in an external resistance of 0·3281 ohm gives $B_n = 9{,}020$ from equation (11). The value of S for constant total potential, from equation (17), will be 6·4 coils.

The necessary additional series coils to give approximate constant external potential at the brushes or at the end of the main leads, and the number of reversed series coils necessary for a drooping external characteristic, are determined by considerations beyond the scope of the present study.

THE NIAGARA FALLS AND LEWISTON ELECTRIC RAILWAY.

On the New York State bank of the Niagara River, between Niagara Falls and Lewiston, a distance of seven miles, a double-track electric railway is being constructed, and for a little over half of its length has been completed and is in operation. From Lewiston, the United States town immediately opposite Queenston Heights, the road for some distance runs along the bank, about 20ft. from the water's edge. As will be seen from our illustration, the side-pole system is used, and the track is of the usual American type. The power for the operation of this road is now obtained from the plant of the Niagara Falls Hydraulic Power and Manufacturing Company, and carried to the point where the road at present begins on cables strung on poles. The cars now start close to the whirlpool rapids, and speed along past the rapids, the whirlpool and other points, affording passengers a truly magnificent view. The construction of the roadbed was a tremendous task. Dynamite was freely used in blasting a path through the rock. In some places the cliff was perpendicular, and at these points the rocky mass was blasted away from the water's edge to the top of the cliff, and the broken rock used to fill in and make a roadbed. Pieces of rock weighing hundreds of pounds were hurled—so heavy were the blasts—clear across the gorge into the Canadian town of Niagara Falls, until the danger to life and property becoming so great, the local authorities of that town made severe protest, and called the attention of the British Ambassador at Washington to the matter. The British Ambassador protested to the State Department, which, in turn, called down the New York State Government, the American local authorities finally preventing further heavy blasts by arresting some of the foremen. The fact that this road runs for miles along the swiftest current of the lower Niagara River, the Company controlling the shore line, has given rise to efforts to develop power from the current, and many men are giving the subject thought, the Company being willing to pay for a plan by which they will be able to secure sufficient power to operate their road.

TESTS OF THE BROWN TELEPHONE TRANSMITTER AND COLLIER-MARR RECEIVER.

The tests described below were made between Baltimore and various other points on the Baltimore and Ohio Railway in the United States, with the Brown loud-speaking telephone transmitter and the Collier-Marr receiver, the patents for which belong to the Single-Wire Multiple Telephone Signal Company. The wires used were the ordinary railway wires used for telegraphy, and the result is interesting as showing that the very great amount of induction present did not interfere with conversation. The same instruments were afterwards used on a railway wire between Chicago and Meadville—500 miles—with perfect success.

September 16th.—Wire in service 182-iron, gauge 9 (rather smaller than English standard gauge 11), to Washington, occupying poles as shown in diagram, distance 41 miles: conversation carried on perfectly and easily at a distance of 10ft. from the receiver during a thunderstorm.

September 17th.—Test made on a single copper wire, gauge 12 (14 English standard), wire No. 40, from Baltimore to Washington Junction, distance 86·3 miles, during a heavy storm of lightning, very heavy induction: conversation easily carried on at a distance of several feet from the receiver.

September 18th.—Raining at Baltimore and all along the line; heavy thunderstorm between Baltimore and Cumberland:—

(First Test.)—Iron wire, gauge 8 (10 English standard), Baltimored to Cumberland, 195·7 miles, earthed at each end: Cumberland could be heard by

Digitized by Google

placing the ear close to the instrument; conversation carried on, but with difficulty, owing to storm.

(Second Test.)—Copper wire, gauge 12 (14 English standard), earthed at both ends: perfectly intelligible speech, although induction very great, the effects of storm quite apparent.

The lines used, besides being parallel or on the same poles as the lines shown in the diagram, are parallel and in proximity to electric light and street railway wires at different points along the line; tests were made when these wires were all in operation, and when the wires on a same set of poles were being used for multiplex and

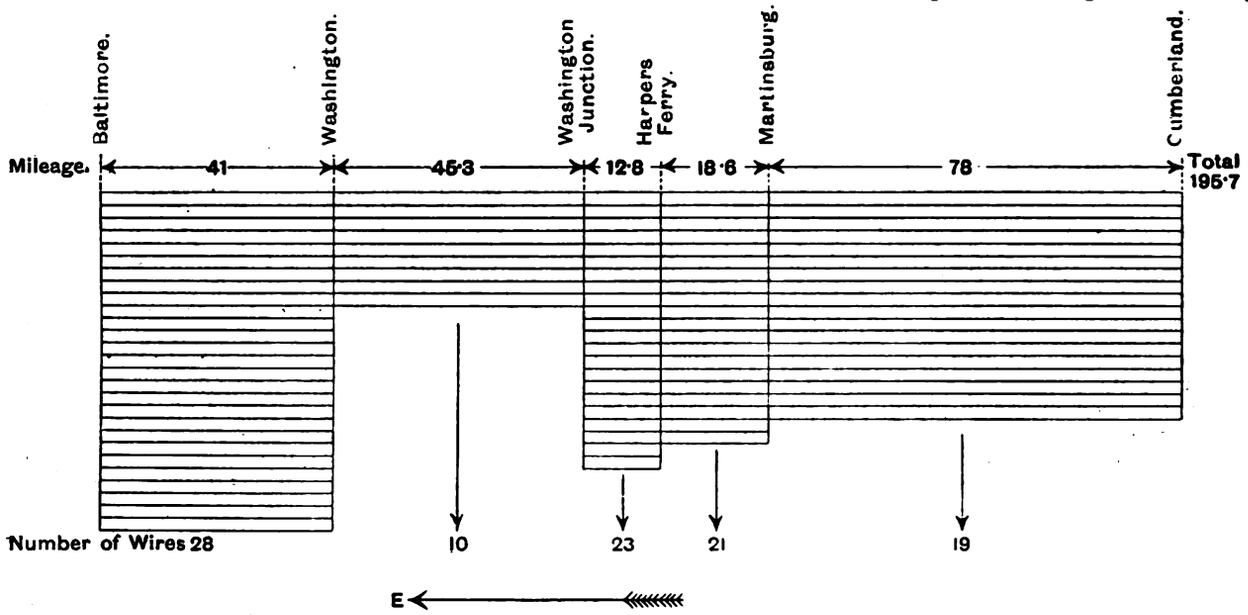

Diagram showing distance and number of wires on poles over which telephone tests with Brown Transmitter were made. (Not drawn to scale).

(Third Test.)—Copper wires, gauge 12 (14 English standard), forming a metallic circuit, Baltimore to Cumberland, distance 195·7 miles: speech perfect, and could be heard from 5ft. to 10ft. away from the receiver.

other telegraphic uses; although the induction was very great, the speech was so clear that when one stood a few feet away from the receiver noises due to induction were not audible.

THE USE OF DUST DESTRUCTORS AS STEAM PRODUCERS FOR ELECTRICITY SUPPLY STATIONS.*

BY E. MANVILLE.

I do not propose to describe all the various methods and systems on which dust destructors have been constructed, as this would involve a Paper so lengthy that it would take more time than at your disposal to read it, and I will therefore only allude to the main points in the arrangement of suitable and of unsuitable systems for the efficient generation of steam by the waste gases from the destructor furnaces, and then confine myself to a description of those two installations at present being erected for the Vestry of Shoreditch and the Corporation of Swansea on what I believe to be the most suitable lines.

The progress of the design of the dust destructor since its first days has certainly been one of slow evolution. In those times the design of the furnaces seems to have been such as to simply provide for the burning, or rather partial burning, of the refuse without much consideration as to the treatment being carried on in a scientific manner, and this, no doubt, has had a great deal to do with the prejudices that still in many places exist against the erection of such an installation within a populous town. These objections were chiefly founded on the smells that proceed from many destructors, and I may assure you that there is no need for such smells to exist. They proceed from two causes: (1) that in some destructor furnaces the design is such that all the gases produced in the heating and burning of the refuse are not thoroughly and completely burnt, and (2) that the refuse when tipped on to the tops of the hot furnaces from the dust carts, before being burnt, rapidly ferments and emits a very sour smell unless proper precautions are taken to prevent this happening.

The first of these two causes which has caused dust destructors in some cases to be regarded as nuisances is due generally to the burning of the refuse at too slow a rate of combustion, and is a fault which is inherent in most of the old forms of destructors, and more especially in nearly all those erected in the South of England. In this type of destructor the refuse is burnt under such natural draught as is attained by a chimney 150 to 180 feet in height, and under this draught the refuse as a rule burns so slowly that its temperature whilst burning rarely exceeds 1,000°F., and is generally below that temperature. When ashbin refuse, as generally composed, is heated to this temperature, gases are given off by its destructive distillation which, to ensure their thorough combustion, must be raised to a temperature of at least 1,200°F. Obviously, if the maximum temperature of the furnace is beneath 1,000deg., these gases are sent out into the atmosphere incompletely burnt and partially causing the nuisance complained of. Therefore, to ensure the complete combustion of all the gases, the mean temperature of the furnace should not be much less than 1,800°F., so that during the operations of clinkering, &c., the temperature of the interior of the furnaces may not fall below the before-mentioned minimum of 1,200°F.; and in the more modern design of destructors these temperatures are obtained through the more rapid combustion of the refuse by burning it under forced draught. In the old types of furnaces where these temperatures are not attained, a secondary urnace has to be provided, in which is burnt continuously a coke-fire, over which all the gases from the refuse furnaces have to pass, and in which their temperatures are raised to the required degree.

Of late years some of the towns in the North of England have set an example as to the use of forced draught so as to produce the requisite atmosphere within the furnaces themselves, and in your immediate neighbourhood there are several good examples of high temperature destructors which leave little to be desired. I allude to those at Warrington, Rochdale, Oldham and at Leeds, in all of which the temperatures attained are amply sufficient to completely burn and thus render completely innocuous all the gases produced by the destructive distillation of the refuse. The use of forced draught has proved itself eminently satisfactory so long as normal conditions are maintained in the quality of the refuse to be burnt; but, at the same time, it is certain that no matter what the locality may be, every single load of refuse cannot be absolutely relied upon to contain nothing of a character that might prevent the necessary high temperatures being attained, and therefore I believe that, especially in small ranges of destructor cells, means should be provided for adding a secondary fire, even if it be only used occasionally when the refuse is of a doubtful character. Proper design and provision of this kind having been made, there can be, I think, no doubt in the minds of those responsible for the erection of dust destructors as to the certainty of complete combustion of the gases taking place, and the entire absence of anything in the shape of a nuisance arising from those gases as sent out into the atmosphere through the chimney shaft. The second possible source of a nuisance—namely, the smell arising from the fermentation of the refuse when tipping within the destructor house before being burnt—is, happily enough, likewise entirely eliminated by the use of forced draught. I need hardly point out to you that the large weight of refuse that has to be burnt hourly requires the provision of a very large quantity of oxygen for its complete combustion, and if this oxygen be furnished in the shape of air provided by fans producing the forced draught, this air can be taken by the fans with the greatest facility, from above the level of the tipping floor, and the rate at which the fans draw air is such that the whole atmosphere of the destructor house is renewed

* Abstract of Paper read before Northern Society of Electrical Engineers.

Digitized by Google

at very short intervals of time, the whole of the air so abstracted being sent by the fans through the furnaces and up the chimney shaft, and in its passage through the furnaces is rendered completely innocuous; thus, the forced draught not only provides for that temperature which is requisite to render innocuous the gases produced by the destructive distillation of the refuse, but also draws into the furnaces the outside surrounding atmosphere that may have been rendered unpleasant to the smell by the fermentation of the green refuse.

The calorific value of burning refuse has so often been called in question, and such varying statements have been made as to the results so far achieved, that there is little wonder at the incredulity of many Local Authorities as to the steam refuse having any value worth talking about from a steam-raising point of view. I am afraid I must state that many of these contradictory statements have been made from sheer ignorance on the part of those who made them and others on account of the conditions under which the steam raising has been performed.

You are no doubt aware of the extremely good radiating properties of brickwork, and you can well appreciate that if a row of furnaces are placed at one end of a long brick flue, and boilers placed at the other end of this same flue, so that the hot gases, in their passage from the furnaces to the boilers, are exposed to a great area of brickwork, a very large proportion of the useful heat of these gases is lost before ever the boilers are reached, and then, again, in most of the older types of destructors the boiler-heating surface provided, on which the gases act, is completely insufficient for the efficient utilisation of this heat. I have myself heard practical users state that but an extremely small amount of steam can be hoped to be produced with their dust destructor, and therefore with dust destructors in general. Now, of course, the calorific value of ashbin refuse varies in every district according to the season of the year and the nature of the district; but, after making all due allowance for such differences as might exist under these conditions, some of these statements set forth publicly seem to me to be quite ridiculous, and I believe this view is held by those who, like me, have taken the trouble to ascertain what may be attained in the way of steam raising with ashbin refuse. I have always endeavoured in such cases to find out the reasons that have induced the gentlemen concerned to place such discouraging figures upon the calorific value of their ashbin refuse, and I have invariably found that the cause was due to the admixture of foreign substances with the refuse collected from the ashbins. I would mention one case in particular, where a gentleman well known in connection with dust destruction has from time to time stated that in his belief no such horse-power as talked about by others could be obtained from ashbin refuse: I found that his ashbin refuse was enormously diluted with street sweepings before it was burned in his destructor. Need I say that it follows that if a matter of an entirely incombustible nature is mixed with—if I may term it—pure ashbin refuse, the calorific value of the ashbin refuse may be so reduced that it may be entirely worthless as a steam producer? But I hope now that the subject is being so largely considered that where the unusual conditions of the admixture of foreign substances with the ashbin refuse occur, those who talk of the steam-raising properties of ashbin refuse under these conditions may be more careful in the future to mention that it is so mixed. I feel strongly upon this point, since to my personal knowledge several Local Authorities who might have erected dust destructors and utilised the steam raised by the combustion of the ashbin refuse have been so discouraged by these contrary and apparently inexplicable statements that they have abandoned altogether the consideration of a destructor scheme.

I will not further take up your time by the discussion of what I may term the principles of refuse destruction, but will rather now proceed to describe to you the methods by which I am engaged in applying it to electric power production.

In the year 1892 the Vestry of St. Leonard, Shoreditch, in London, had in view the erection of a central electric supply station and at the same time of a dust destructor. I being appointed to advise the authority in relation to electric lighting, strongly recommended them to combine the two schemes. A great deal of careful investigation was carried out on their behalf to ascertain what power might reasonably be expected as obtainable from the burning of their ashbin refuse, and as a result of this investigation I felt enabled to assure them that all the steam required for the estimated electrical output likely in the first instance to be demanded from their electric light station might be obtained from a properly designed dust destructor, without the use of other fuel. In arriving at this opinion I experimented on a large scale with samples of ashbin refuse collected from various parts of Shoreditch at a season of the year when household fires were not much in use, and I found it was extremely rich in carbon.

When the unsorted refuse was burnt directly in a boiler, it evaporated as much as 3lb. of water from and at 212°F., and my opinion that the steam required could be obtained from the burning of this refuse in a properly-designed arrangement of destructor cells and boilers, was founded on the supposition that only about one-third of the calorific value of the refuse would be utilised in the boilers, after due allowance had been made for the complete and perfect combustion of the ashbin refuse and its gases.

The Vestry thereupon resolved that such a combination should be erected forthwith. Unfortunately the scheme approved of by the Vestry in the early part of 1893 did not advance with the speed one might have hoped, owing to the difficulty of obtaining a sufficiently extensive site within the area of the parish, more particularly as the Vestry wished to erect on the same site other municipal buildings. This difficulty having at last been overcome, about eight months ago I was enabled to proceed with the plans of the arrangement originally proposed by me. A number of tenders were received for carrying these plans into effect, and ultimately the contract was awarded to Messrs. Manlove, Alliott and Co., of Nottingham, on the following basis, and this firm are now actively proceeding with the construction of the works.

The destructor cells themselves are arranged a pair on each side of a Babcock and Willcox boiler, there being thus in all six boilers. Each of these boilers has a heating surface of about 1,400 sq. ft., and a pair of cells on each side of it are arranged to discharge their products of combustion under the boiler tubes immediately above the level of the fire bars, these fire-bars being left in the boiler together with the fire doors in exactly the same manner as if the boilers were being erected without the accompaniment of dust-destructor cells. Each cell is arranged with double flues, one leading to the boiler, as aforesaid, and the other direct to the main flues.

Each destructor has a grate area of 27 sq. ft. The main flues are arranged above the floor level and underneath the working floor, and are in duplicate, each boiler and cell being able to discharge its gases into either or both of the main flues. This arrangement of duplicate flues is essential in the combination of a dust destructor with an electric lighting station, as the dust carried over with the products of combustion from the cells into the main flue must be removed at moderately frequent intervals, whilst the working of the main flue can never be discontinued owing to the necessity of continuous steaming of the boilers, and this duplicate arrangement of the flues enables one flue at a time to be cleaned out, the products of combustion of all the boilers and all the cells being taken into the remaining flue during that time. At the end of the main flues is placed a chamber, which for the present will serve the purpose of a dust-depositing chamber, but may in the future be divided up to contain an economiser with its requisite by-pass flue. This chamber leads into the main chimney shaft, which is 150ft. in height from the floor level, and is provided with a circular gallery around its base, into which this chamber leads, and between which gallery and the main shaft are a number of small openings, the whole being so arranged that the products of combustion have to swirl round the gallery to enter the shaft—a provision to ensure the final depositing of any fine dust carried by the gases through the depositing chamber. The chimney shaft is lined right to the top with fire-brick, and a ventilated air-space left between the fire-brick lining and the main structure of the shaft, to avoid the outer walls being appreciably heated. In the London district this is quite desirable, since the rules of the London County Council provide for such thickness of walls in the chimney shaft that the unequal expansion and contraction of these walls would be such as to lead to the disintegration of the brickwork, the inner skin coming into contact with gases possibly at the temperature of upwards of 2,000°F.

As before mentioned, each Babcock and Willcox boiler has its proper complement of fire-grate, fire doors, &c., which are provided for the express purpose of enabling the boilers to be fired by coal alternatively or simultaneously with the absorption of heat from the waste gases of the destructor cells passing through the boilers. This arrangement fulfils a two-fold object. Firstly, the provision of the secondary fire before referred to, which is in the most desirable position for further heating the destructor gases immediately they enter under the boiler, should that operation be requisite, and having the further advantage that the heat so produced is ultimately completely absorbed by the boiler and thus turned into profitable use; secondly, to add to the steam-raising power of the boilers when the heat of the destructor gases is not sufficient to produce all the steam required, or when the destructor cells attached to a particular boiler are out of order, to enable the boiler to be entirely fired by coal or coke.

Each of the destructor cells and the boiler furnaces is fitted with two systems of forced draught, one being an air blast, the other an induced blast produced by steam jets. The air blast is produced by three sets of fans coupled to and driven by electric motors, two out of the three fans being sufficient to supply 16,000 cubic ft. of air per minute, the maximum quantity that could possibly be required, and to produce it at a pressure up to three-inch water gauge. The steam blast is derived direct from the boilers, and is arranged as a continuous system, so that cells adjoining a boiler

Digitized by Google

not in use can still obtain their steam blast from the other boilers in use. So much divergence of opinion still exists as to the relative merits of the fan blast and induced steam blast, that the Vestry, acting under my advice, settled to instal both systems, when they will be able to use either or both in combination as may be found desirable in practice.

Ten out of the twelve dust destructor cells are capable of burning with ease the 20,000 tons of ashbin refuse which have to be dealt with by the Vestry annually. The charging of the cells with refuse is to be effected in a manner which, though not novel, will perhaps be more effective than heretofore. The space available for the construction of an inclined roadway involved the use of a gradient of one in fifteen—not an unusual gradient for such purposes, but at the same time decidedly detrimental to the longevity of the horses drawing the carts, and it was decided to replace the elevated roadway with two electric lifts. Either of these lifts is capable of lifting a full load of, say, three tons of refuse, and being in duplicate, no hindrance can happen to the delivery of refuse should one of them be put out of order. The refuse is tipped from the carts into a tipping wagon, sinking below ground level, and raised by the lifts afterwards to a floor considerably above the level of the tops of the dust destructor furnaces. These tipping wagons are then hauled by mechanical means into any desired position along the range of furnaces, and the refuse tipped from them into storage bins reaching from this floor to the level of the tops of the destructor furnaces. From these storage bins the refuse is discharged as required into charging trucks made after Messrs. Bulnois and Brodie's patents. These charging trucks are divided into compartments so arranged that the charging truck being brought over a horizontal door in the top of and at the back of the destructor cells, doors in the bottom of the truck corresponding with each compartment may be opened simultaneously with the door at the top of the cell, and the exact charge of refuse dropped through in to the cell. There it falls upon an inclined hearth at the back of the fire grate, whence it is raked down through the clinkering doors in front on to the fire grates themselves. This arrangement enables a great deal of manual labour to be dispensed with, the whole of the transference of the refuse to the particular destructor it is destined to feed being accomplished by means of electric motors, and the storage bins referred to have a capacity equal to sixty tons of refuse, which will enable the furnaces to be fed during the night time, and also during the greater portion of the time that intervenes between Saturday afternoon and Monday morning. The storage bins being placed well above and out of contact with the hot brickwork of the destructor cells, the stored refuse is preserved under the most favourable conditions.

As mentioned previously, the principal object of the whole of this arrangement of boilers and cells is to get a maximum output of steam. I have calculated that the electric light station will require steam at 120lb. pressure at the rate of 12,000lb. per hour for four hours a day, 6,000lb. per hour for three hours a day, and 2,000lb. per hour for the balance of the 24 hours, or in all 100,000lb. weight of steam for twenty-fours.

The contractors who tendered for the carrying out of the works were invited to state what proportion of this weight of steam they would guarantee should be raised by the consumption of ashbin refuse only. Many of them, including Messrs. Manlove, Alliott and Co., undertook that no coal should be required to raise the requisite amount of steam daily. It must be borne in mind that the chief difficulty to be met in the combination of a dust destructor with an electric lighting station, from a steam-raising point of view, is that while the refuse is being burned at an approximately even rate during the whole day, the steam for the electric light station unfortunately is required in very varying quantities, varying from a very small quantity during the greater portion of the day to a maximum at least six or seven times the minimum during the four hours of heavy load; and whilst the furnaces might be quite capable of raising the total quantity of steam required at an even rate, they might be incapable of raising the quantity required during the four hours of heavy load. To meet this difficulty Messrs. Manlove, Alliott and Co. propose to instal in conjunction with the boilers the patented thermal storage system of Mr. Druitt Halpin, and the arrangement of thermal storage reservoirs proposed for Shoreditch is shown on the accompanying sketches. Seven reservoirs, each 35ft. in length and 8ft. in diameter, are provided and connected up to the boilers, thereby accumulating the energy. The temperature in the reservoirs is never allowed to drop below the equivalent of 120lb. steam pressure to the square inch, but, during the accumulation of the energy developed by the boilers, the temperature is raised in both the boilers and these reservoirs until a temperature equal to a pressure of 200lb. per square inch is attained. When in each day the time of heavy load is attained at the central station, both the boilers and these reservoirs feed into the steam mains supplying the engines, and as the energy taken by the engines considerably exceeds that which the boilers are capable of generating, the pressure in boilers and reservoirs gradually falls until a minimum of 120lb. is again reached, and the energy represented by this difference in temperature is that which has been taken up from the boilers during the daytime by the thermal storage reservoirs. Thus is the energy that would otherwise be wasted accumulated and carried on to the time when it can be utilised by the electric light engines. An additional and not unimportant advantage accrues from the use of these thermal storage reservoirs, inasmuch as the feed water is pumped into the reservoirs and not into the boilers, and hot water at the actual boiler pressure is allowed to gravitate from the reservoirs into the boilers to make up for the evaporation in the boilers. At the minimum temperature at which the storage reservoirs are standing, practically all the inorganic salts held in solution in the water are deposited in the reservoirs, and the boilers are fed with water free from these impurities. They therefore remain perfectly clean and unscaled on their water surfaces, and are always working at their highest efficiency, whilst the precipitate in the thermal storage reservoirs is in the shape of soft mud only, since the plates of the reservoirs are not exposed to the action of the fire, and they can be with perfect facility cleaned from this precipitated mud.

The combination of a thermal storage system with a set of dust destructors and boilers will, I believe, appeal to all of you as an ideal arrangement for the utilisation of the steam produced by the latter.

You will notice that very high pressures are to be attained, 200lb. being the maximum.

I have myself heard Papers read before societies in which it has been stated that higher pressures that 70lb. or 80lb. cannot be attained in boilers fired with destructor gases. Statements of this kind do not require much comment from me. It will be obvious to all of you that with destructor gases varying from 1,200° to 2,000°F., such a pressure as this, or, indeed, if it were desired, a much higher pressure of steam, can be obtained. Perhaps those who have made such statements will be reassured when they find a firm of standing guaranteeing, under heavy penalties, the successful issue of a dust-destructor thermal storage scheme in which a pressure of 200lb. to the square inch has to be attained without the use of coal.

A somewhat similar system is about to be erected now under my superintendence for the Corporation of Swansea, the chief differences in this scheme being that only 8 in place of 12 destructor cells are being put up, with four boilers, each, however, in this case with a total heating surface of 2,896 sq. ft. No thermal storage cylinders are for the present being connected to this installation, though provision is being made for their addition at a future date when the load on the station makes it desirable. In this case also the electric lifts are not being used, as the general configuration of the site allows of an easy inclined roadway being constructed for the up load. In all other respects the installations are almost identical.

Having now described these two installations, which are, so far as I am aware, the only complete schemes at present in progress of construction, I should like, if I am not infringing too much upon your patience, to show you what magnificent results may be obtained from such an installation, given a condition of day load which I hope will often occur in the future.

A very interesting Paper was read before this Society last year by Mr. Gibbings, of Hull, in which he pointed out to you the great use that might be made of a destructor for charging accumulators for tramcar service, and of the immense effect it would have on the total costs of production of electricity with interest and sinking fund of capital charges. At that time I informed you that a project was on foot by which the Swansea Corporation hoped to be enabled to supply all the tramways within their own town with electricity generated at their own electric lighting station. This has now become a definite scheme, the Corporation having arranged the preliminaries of an agreement with the Tramway Company. The Tramway Company will ultimately have about 25 cars simultaneously in operation, and these cars will between them run annually an estimated car mileage of 1,000,000. It is a matter of common experience that an electric tramcar takes in an average town a Board of Trade unit for each car mile run, and therefore the output of supply to the Tramway Company will be 1,000,000 units annually. On the basis of the arrangement proposed between the Corporation and the Company, it is estimated that the latter will be supplied with current at about 1½d. per Board of Trade unit conditionally upon the supply being made only during 20 hours of the day instead of 24, the other four hours being those of the heavy lighting load, and to carry the Tramway Company over this period a stationary battery of accumulators will be installed of sufficient capacity. The revenue from this million Board of Trade units represents a sum exceeding £6,000 annually, and it is remarkable that it will be earned with one plant running during the day and late at night time, with an output of about 200 kilowatts. In other words, it will be earned by the same machinery that would in any case be running during the hours of daylight to keep the mains charged, and earning practically no revenue. It

Digitized by Google

follows also that the cost of producing this extra million Board of Trade units will be only some additional oil used on the engine owing to its running at full load in place of at an extremely light load; no further charges for attendance, and possibly a small extra amount annually for repairs, though this is doubtful.

Since, therefore, the whole of this large output is produced at an extremely low additional cost, the station and destructor can be run paying all its maintenance charges, as well as interest and sinking fund for the production, not only for the million units day load, but of 350,000 units for public and private lighting, and the cost of attending to the public arc lamps at no extra cost, leaving the revenue derivable from these sources as net profit. It will therefore be feasible for the first time in this country to sell electricity for private lighting purposes at 2d. per Board of Trade unit and to make no charge for the current used for public lighting purposes. I need hardly point out to you that with gas at 3s. 6d. per thousand feet, the price in this town, electric lighting will, under these conditions, be much cheaper than gas.

In considering this apparently Utopian position, you must not fail to bear in mind the fact that the ability of the Corporation to supply this large day load at a price attractive to the Tramway Company is solely due to the use of the dust destructor. For, had the Corporation to pay for the fuel, their costs of production, with the stoker's wages, would be raised by nearly one penny per unit. This would then raise the price of the supply of current to the Tramway Company to a point at which it would be more profitable for the latter to erect their own generating station.

I will not further detain you, and in concluding hope that you will agree with me that the successful combination of dust destructors with electric lighting is in this way likely to produce a complete revolution in the prospects of electric lighting in this country.

DISCUSSION.

Mr. CALVERT said: First of all there was one thing regarding the practical application of the burning of refuse. If Mr. Manville had taken into consideration the damp fuel that they would have to contend with, he thought from his own personal knowledge of burning damp stuff in boilers that the corrosion was so great that it considerably increased the wear and tear of the boiler. Then there was a point on thermal storage. When that subject was first heard of some time ago it certainly appealed to him as being a matter of importance, but on going into it he could not exactly find where the advantage came in. On reading Mr. Manville's Paper through he made a few calculations, and would ask for some information respecting them. As regards the first point, the horse-power required would be 400 H.P. for about four hours. He calculated that the heat stored in Mr. Manville's seven cisterns was 900 H.P. for four hours. How much they would get out of the 900 was the question, on account of the loss of heat by radiation. Possibly Mr. Manville had gone into that subject, and could answer it better than others who had not had experience. Another point which presented itself was that on the one hand with the storage system the storage plant would cost something like £3,000, and further they had to take into consideration that all the boilers would have to be built for 200lb. pressure of 120lb. The 400 H.P. which they required for 4 hours, or about 600 hours per annum, could easily be got out of Lancashire or Babcock boiler, which would cost something like £400. The cost of fuel for, say, four hours per day for about eight months in the year would, reckoning roughly, come to about £200. £200 per annum would scarcely be interest and depreciation on the large items which would be expended providing his calculation was right. He could not see where the advantage of this thermal storage came in, and he had made the remarks in the hope of getting some information, which would be of the greatest interest to everybody there that night, on which he thought was the question of the day, *i.e.*, thermal storage *versus* battery storage. Mr. Manville had given them his views as to the reduction of the cost of production of electrical energy by the burning of refuse. Mr. Manville calculated 2d. per unit. The cost of steam production for electric lighting was something like three-eighths of a penny per unit. Whatever Mr. Manville could do, he could not save more than this, and he did not see where the reduction of 2d. per unit came in. In the thermal-storage question it was evident that only the boilers had the advantage of storage, as of course the engines and dynamos must all be there just as well as in an ordinary plant without storage.

Mr. LONGRIDGE said that, having no practical knowlege of destructors, he had come to the meeting to receive rather than to give instruction, therefore he could not presume to offer any serious criticism of the Paper, but would confine himself to mentioning one or two points which had struck him on reading it. So far as he could gather from the author's figures, there seemed to be from 30 to 35 per cent. of carbon in the refuse. This seemed to him a high percentage, and he thought that if the fact were brought home to householders they would, in many cases, take steps to reduce the waste. But whether they applied their minds to cinder sifting or not, it seemed to him that if, as the author suggested, current could be supplied at 1½ per unit, everyone would use electric light, and the gas companies would have to sell their gas at a low rate for cooking. If such a desirable consummation were reached, the kitchen fire, the mine from which the author probably drew a very large percentage of his fuel, would be put out, and the percentage of coke in ashpit refuse would be considerably less than it seemed to be at present. Another alteration was that the refuse might rise considerably in price. Some years ago coke breeze could be bought in London for 2s. 6d. a ton, but as soon as the means of burning it satisfactorily in steam boilers became known, the price, with the demand, began to rise, and now it had reached 7s. per ton, a price at which it was nearly as dear as its alternative small Welsh coal, having regard to the plant and labour required to burn it. The author had stated that there was difficulty in burning ashpit refuse in the earlier destructors, and that it was only when the temperature was raised by forced draught that destructors became a practical success. He was not surprised at this. To his mind high temperature in the furnace was the essence of the matter. If this were attained he was confident there would be no difficulty in effecting complete combustion. He was surprised how anyone with the blast furnace before their eyes should either hope to work a low-temperature destructor successfully or should doubt the satisfactory working of a high-temperature one. It seemed to him that the success of a destructor was merely a question of sufficient blast. This brought him to the third point which had struck him, namely, the unusually large grate and heating surface provided for the work to be done. As far as he could make out, it was intended to burn from 10lb. to 19lb. of refuse per square foot of grate. He could not see how with such a rate of combustion they could get high temperature desirable specially with a forced draught of 3in. The grates could not be kept covered. The heating surface also was enormous for the power required, which he understood was about 400 H.P. With an apparatus of these proportions he feared the interest in capital would make the scheme, otherwise admirable and interesting, a financial failure.

Mr. TINKER said both the Shoreditch and the Swansea schemes appeared to him to have been most carefully and skilfully worked out in every detail, and he did not doubt but that great success would result from the general arrangement decided upon.

Mr. J. H. RIDER said: With regard to the ash-bin refuse he wished to know whether before it was put into the hoppers it would have to be sorted. Ash-bin refuse was of a very mixed character. It seemed to him that the sorting would entail labour, and labour cost money, and he would like to know how that labour brought up the cost. He was burning at present only coke breeze, and if the price would go up to such an extent as Mr. Longridge said, there was a bad time coming for him, as he was getting it at present for 2s. 6d. a ton. His fuel bill had never been over 0·5d. per unit since using breeze, and last month it was only about 0·35d. If he used refuse, how would the cost of production compare with that? With regard to the thermal storage, he was actually ignorant of thermal storage, and if he should say anything that was absurd, he hoped they would pardon him. In Mr. Manville's scheme they had six or seven very large boilers. Unless these boilers were covered in a very marked degree, the loss of heat would be very great, and so far as he could see they had no external method whatever of keeping up the heat. He did not know how any composition would answer, and would like some information on that point.

Mr. S. V. CLIREHUGH said that he would like to put before the members some tests which were brought under his notice which were carried out in Yorkshire with a refuse destructor. These tests were carried out in order to enable some idea to be formed of the calorific value of refuse in various towns. The refuse was not treated in the most approved style as it was burnt under ordinary Lancashire boilers. Some interesting facts, however, were brought to light with regard to the bye-products which might be obtained. The refuse came in truck loads of about six to eight tons at a time, and it was simply tipped on the floor of the destructor house. It was then taken up by an endless belt through a large sieve which collected the old kettles, tin pans, &c. The remainder was passed into a revolving drum through which gases from the furnace passed before going up the chimney. After leaving this drum the refuse was passed through a fine sieve and the very fine portion of it was allowed to fall down into sacks while the remainder was carried to the front of the boiler and burnt. The results were rather curious, the following being the average result. They found that the amount of water evaporated in the hot cylinder was 25 per cent. on the total weight of the refuse treated, and that only 40 per cent. arrived as fuel in the furnace. They got with 1lb. of treated refuse 5½lb. of water evaporated. Mr. Manville had obtained 3lb. of water evaporated with untreated refuse, that is, containing 25 per cent. per cent. of moisture, so that the results were approximately near one another. The actual results obtained from one ton of refuse were as follows: Fuel, 40 per cent.; dust, 25 per cent.; rags, 6 per cent.; tin pans, &c., 3 per cent.; water, 25 per cent.; sundries, 1 per cent. They found, on analysing the fine dust that it was valuable manure, which sold readily in that district from 9s. to 10s. per ton. Therefore, from one ton of refuse treated they obtained the following:—Dust, 25 per cent. 2s. 6d.; rags (at ½d. per lb.), 5s. 6d.; making a total of 8s. per ton. If Shoreditch Vestry could obtain this price it would amount to the substantial figure of £8,000 per annum. Of course they could not find a market for such large quantities, but in smaller town they could probably dispose of it. With reference to Mr. Calvert's remarks, he said that even were the whole ⅜d., which he assumed coal now cost, saved they could not improve on this. He would point out, however, that they could do very much better than that since the local authorities would be willing to pay something for the destruction of the rubbish. He would like to add, with reference to the question of sorting, that the whole of this, in the system he mentioned, was done mechanically, and the refuse was not at any time touched by hand.

The Last Horse Car at Detroit.—The running of the last horse car in Detroit, U.S.A., prior to working the tramways entirely by electricity, was made the occasion of a great public demonstration. After the trip was concluded the car was torn to pieces by relic hunters, while the team of horses was auctioned off and sold for $100.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

CHRISTMAS WEEK NOTICE.

"THE ELECTRICIAN" will be published as usual on Friday in Christmas week, but as the Offices will be closed on Wednesday and Thursday it will be necessary that Contributions, Correspondence, News Items and Advertisements should reach the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London, by, at latest, Tuesday's post.

DUST FUEL.

Among the many and varied suggestions which have been put forward for reducing the works costs of electric supply stations, one of the most notable is the scheme for the utilisation of town dust-bin refuse as fuel for steam raising. This scheme practically involves the union of a dust destructor works with an electric supply station, the combined works being preferably, though not essentially, under the control of the local urban authorities. We feel sure, therefore, that many of our readers will peruse with interest the abstract of a Paper by Mr. E. MANVILLE on "The Use of Dust Destructors as Steam Producers for Electricity Supply Stations," which we publish this week. There is probably no one who could give us more information on this subject than Mr. MANVILLE; and it is gratifying to find that in his Paper he has drawn a little upon his fund of experience, acquired in connection with the Shoreditch and Swansea schemes. Naturally the author of this Paper holds sanguine views in regard to the success of these two schemes in particular, and the generation of electric energy by the aid of dust-bin refuse in general. But he has formed his opinion upon a number of data which it would be difficult to controvert; and, as he points out, the fact of a firm of contractors of high standing having guaranteed, under heavy penalties, the successful issue of the Shoreditch dust-destructor thermal-storage scheme, should be in itself somewhat assuring to those who may have doubts about the matter. Not that there is no longer any room for doubt about the commercial possibilities of dust fuel. Hitherto there has been no extensive experiment in this direction, and the existing schemes must be based upon the evidence of more or less indirect facts. Yet these facts, are in the main, we think, such as may legitimately be made the basis of an experiment on the scale proposed for Shoreditch or Swansea. For instance, although we may not be able to dogmatise about

Digitized by Google

the capabilities of a district to obtain light from its own dust refuse, it is quite a simple matter to estimate the volume and the temperature of the gases issuing from any given destructor in a day, or a month, or a year; and therefrom to estimate the weight of steam which may be generated in an efficient battery of boilers. We cannot ignore the existence of many grave and important difficulties attending the working out of a dust-utilisation scheme for electric supply, but it is impossible not to admire the thorough manner in which these difficulties have been faced, and the ingenuity with which it has been sought to overcome them, in the two schemes already referred to.

Some of these difficulties were brought forward during the discussion on the Paper. There was the usual practical, pointed character in the discussion, so commonly a feature of the Northern Institution and so rarely a feature of discussions in the Institution in London. One speaker commented on the trouble which might arise from excessive wetness of the refuse. Another speaker confirmed Mr. Manville's own estimate that this wetness would usually be about 25 per cent. The trouble with wetness is not merely that it has to be evaporated, but also that it corrodes the boilers and shortens their life. A speaker put his finger on the weak point in thermal storage, viz., the increased prime cost which it involves as against battery storage; and the chances of considerable loss of heat from the thermal storage cylinders were also discussed. It should not be forgotten that these cylinders can be completely surrounded by non-conducting composition, and on that account are more favourably situated than ordinary boilers. In regard to the capital cost of the destructors and such matters as the cost of sorting the refuse, it is hardly fair to saddle the electric supply system with these; since they are as necessary without as with an electrical appendage to the destructor works. Mr. LONGRIDGE drew a humorously sad picture of the downfall of electric-refuse-destructor works, from causes arising from their own prosperity. If their could supply electricity so cheaply as had been said, the gas companies would be obliged to bring down the price of gas to such a low figure that every housewife would adopt gas fires and abandon coal fires. And then there would be no cinders in the dust bin, and *ergo* no fuel for the electric-refuse-destructor works. It is a sorry reaction to contemplate!

Two considerations have to be kept in view in arranging for the generation of electric power by means of dust fuel. On the one hand, the fuel must be consumed consistently with sanitary requirements, which will generally mean that the furnaces will have to be fired at a steady rate. On the other hand, it will be necessary to utilise the steam according to the variations of the electrical load. These apparently are conflicting conditions; but they may be reconciled in three ways. The first way—the least to be commended—is to combine the dust-fuel steam generators with ordinary coal-fired boilers, or to mix coal or coke with the dust itself. The second plan is that to be used at Shoreditch, and consists in using some form of storage system, whereby the surplus energy developed in the destructors may be stored against the time when the dynamos will be heavily loaded. At Shoreditch the system of thermal storage invented by Mr. Druitt Halpin will be in operation; but it would be quite possible, perhaps preferable, to have electrical storage. The latter would have the advantage of equalising the work of the engines and dynamos, as well as of the steam generators. The third plan is the most desirable of all, and consists in the provision of such an ample and regular day load that the energy of the destructors will be utilised almost as it is generated. This, we are glad to say, is the plan just adopted at Swansea, where it is intended that the tramcar load and the electric light load shall be taken by the same generators. At the close of his Paper Mr. MANVILLE makes reference to this system, which, we think, will shortly become a more common feature of electric supply in this country. No doubt this extension of useful work on the part of a largely idle lighting station will be facilitated now that the Board of Trade has decided upon raising the standard of low pressure to the pressure usually employed on tramway systems—viz., 500 volts. On the basis of an arrangement only just made between the Swansea Corporation and the local tramway company, Mr. MANVILLE estimated that about one million units will be supplied annually by the former to the latter at 1½d. per unit. We scarcely agree with the author that all this large output is going to cost the Corporation "only some additional oil used on the engine, owing to its running at full load in place of an extremely light load; no further charges for attendance; and possibly a small extra amount annually for repairs, though this is doubtful." Mr. MANVILLE apparently contemplates adopting no unit of less than 200 kilowatts. But it seems to us that were a tram load not in anticipation the plant would be more sub-divided, and a decidedly smaller unit would be running all day, taking attendance and oil and running up the bill for repairs. Indirectly, therefore, the provision for a tram load will include other items of expense than those to be found in Mr. MANVILLE's list. Besides, with so heavy a day load, will coal or coke *never* have to be burned in the daytime?

We confess that our imagination boggles somewhat when we try to follow Mr. MANVILLE's roseate prophecy of the future electrical millenium at Swansea. In the first place, we are told that the tramways will have their supply cheaply because the extra cost of running the plant by day will be so trifling. For this reason the absurdly small levy of 1½d. to 2d. per unit will be made. So far it is all very simple, and, if Mr. MANVILLE's data are correct, we see that a revenue of £6,000 might be derived from the tramway supply. But we are next told that this sum will pay all "maintenance charges, as well as interest and sinking fund for the production, not only of the million units day load, but of 350,000 units for public and private lighting, and the cost of attending to the public arc lamps at no extra cost, leaving the revenue derivable from these sources as net profit." In other words, the supply to the trams is to be so ridiculously cheap because the lighting will bear all the expenses, and the lighting is to cost nothing at all, and to be all profit, because the tramway supply will rake in such a nice lot of money. Between the two jobs, the trams by day and the lights by night, the station is going to supply 1,350,000 units at an average price of 1·65d. per unit!

ANNUAL GENERAL MEETING OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the Annual General Meeting of the Institution of Electrical Engineers, held at the Institution of Civil Engineers, Great George-street, on Thursday evening, the President (Mr. R. E. B. Crompton) occupied the chair. The Report of the Council having been read, the PRESIDENT remarked that the Institution might congratulate itself upon having assisted in the very satisfactory Conference with the Board of Trade alluded to in the Report, and then moved "That the Report of Council as read be received and adopted, and be printed in the *Journal* of the Proceedings of the Institution." Prof. PERRY seconded this resolution.

Mr. J. RAWORTH said, before proceeding to the adoption of the Report, he had it on his mind to say a few words. He congratulated the Institution and the Council upon the excellent

Digitized by Google

nature of that Report and upon the general prosperous condition of their affairs; but to him it was a matter of regret that the Report had not proceeded to ask the members of the Institution to grant to the Council greater facilities for obtaining the advice and assistance of the members on matters affecting the welfare of the Institution. He approached the subject with a deep sense of responsibility—he did not speak merely upon his own behalf, for he was well assured that he represented the feelings of a large mass of the members of the Institution—and he trusted that his sense of responsibility was commensurate with the greatness of the subject with which he was about to deal. He sometimes wondered whether their various members really rose to a full appreciation of the magnificence of the Institution. It was respectable in its origin, it was remarkable in its progress, and its destiny would be resplendent. They had seen what had been the course of the Institution of Civil Engineers, and it filled their minds with respect, almost with awe, when they considered what a moving force it had been in the civilised world; but that Institution had arrived at, or nearly at, the zenith of its importance and power, whilst the Institution of Electrical Engineers had no zenith until at last they had discovered what was the zenith of electrical science and practice. But it was not the question of prophecy that he was disposed to enter upon that evening. At the head of the Institution they had a great and noble Council of which they were all proud, and which did honour both to the Institution and to the profession with which it was connected. But there was one great defect about their relationship, and that was that the two bodies, the Institution and the Council, were two separate entities, and each was pursuing its own existence without knowing what were the desires and the aspirations of the other. The Institution came into existence some 23 years ago, under the presidency of Mr. C. W. Siemens, afterwards Sir William Siemens. It had a membership of something like 100 members, and had a Council, and that Council had developed into the present Council. That Institution of 100 members had developed into an Institution of something like 1,700 members; but there had been a very slight influx of new blood or of members of Council derived actually from the initiative members of the Institution. The two bodies had grown up together, and they were not intercalated. There was a very great danger in this. They had not arrived at the point of danger, and it was in the interests of the Institution, as long as there was a conceivable source of danger which might at any moment culminate in an actual, tangible danger, to consider whether there was any possible method of removing that possible source of danger, so that the future history of the Institution might be unclouded. He was extremely sorry to hear it, but it was a fact that in the past if anybody who took an interest in the progress of the Institution ventured to express his opinion, and that opinion did not happen to be exactly the opinion of the Council, he was liable to be called a "malcontent." He was prepared to deny that they were malcontents in the broad meaning of that term—that was to say, in the sense that it was impossible to please them. On the contrary, he thought they were very easily to be pleased. He wanted to call their attention to one fact in this connection, because it illustrated his meaning, perhaps, better than any theory. It was within the memory of some of those present that at one time there was a question at issue between the members of the Council and some of the members of the Institution; at all events, the Council were prepared to take certain action in which a large number of the members did not approve. It seemed to those members very natural that they should ask two or three of their number to call upon the Council and give them a few words of advice in an informal way as to what would be the best course to pursue. They would, perhaps, scarcely believe him when he said that they found it extremely difficult to get the ear of the Council at all. Eventually they did get the ear of the Council, and naturally the first question put to them was, "Whom do you represent?" The answer, of course, was that they represented no one but themselves, and whilst they had not an express authority to act, they were perfectly certain of themselves and nearly certain of everybody else. That was an unfortunate position for a deputation to be in. But if there was a feeling on the part of that meeting that there was the possibility of some risk arising in the future owing to the fact that the Council was not always thoroughly in touch with the feeling of the members, then they ought to organise some direct means of bridging over the difficulty, and without discussing further the general question he would suggest that it would be an advantage if the Council had the opportunity of quite privately taking the feeling of the members through the voice of a Special Committee. It would be quite naturally urged that they did not want such a Committee, because their Council was their representative Committee. Of course, if that were the case, the answer would be complete; but he held that that was not the answer to the proposition. The fact of the case was that the Council consisted of 15 movable members, 4 vice-presidents, and 13 past-presidents, so that there were 17 permanent stuck-fast members of the Council who not only had a voice but could vote on the Council, and only 15 active, movable members who had any communication with the members at large and who were drawn from the body of the members within a reasonable time. He did not think the members of the Institution were generally aware of that fact; he did not think they were aware that whilst in the Civil Engineers a certain proportion of the past-presidents did not vote, in this junior Institution the past-presidents did vote, so that they had a more vigorous House of Lords than the Civil Engineers. So far as voting power went, it did not matter whom they put on the Council provided the conservative instinct prevailed, and it could not fairly be said that the Council represented the members. It did not represent them in the sense that a Committee would, if they selected a number of gentlemen from that meeting and asked them to go and talk to the President upon any matter in which the members took particular interest.

Now he had had enough of that very unpleasant business, which it had cost him a considerable pang to allude to. Now he had a much pleasanter matter to turn to. They had had placed in their hands that evening a balloting paper, and he thought that paper must be a source of intense gratification to the members. He found that the Council proposed to elect Mr. Sidney Morse an associate. He thought the Council there had got on to bed rock, for it had chosen an associate who occupied a very exalted position on what he might call the outer ring of the electrical industry. Further, he could not sit down without expressing his satisfaction, and that of every member who had spoken to him on the subject, on the selection by the Council of Dr. Hopkinson as President. He would conclude by proposing this resolution: "That this meeting considers it desirable, in the interests of the Institution, to form a Committee to represent the views of the members in consultation with the Council, and such Committee is hereby constituted of the following members: Mr. A. A. C. Swinton, Mr. E. Manville, Mr. R. P. Sellon, Mr. A. B. Holmes, Mr. W. P. J. Fawcus, (Manchester), Mr. A. W. Heaviside (Newcastle), Mr. H. A. Mavor (Glasgow), and Mr. J. C. Vaudrey (Birmingham), with power to add to their number."

The PRESIDENT asked whether Mr. Raworth intended his resolution as an amendment to the Report or as a substantive motion.

Mr. RAWORTH: It practically constitutes an amendment, but if you like it may be put as a separate motion.

The PRESIDENT: Well, say one thing or another.

Mr. RAWORTH: We will put it as a separate resolution.

The PRESIDENT'S motion, that the Report of the Council be received and adopted and printed in the *Journal* of the Proceedings of the Institution, was then put and carried unanimously.

Mr. G. L. BRISTOW, the honorary solicitor, said he had read the resolution, and he was afraid it was not within the powers of the Annual General Meeting to do what was proposed in it. The business which that meeting had to carry out was stated in Clause 55 of the Articles of Association, and provided that "the Annual General Meeting of the Institution shall be held at the meeting next previous to Christmas Eve, and the business of the meeting shall be to receive and deliberate upon the Report of the Council as to the state of the Institution and to elect the officers for the ensuing year." That seemed to be the only business which it was competent for that meeting to transact. If they desired to pass a resolution of this sort, it should be done at an ordinary general meeting after notice. He took it that the resolution was not designed in any way to alter any of the rules or regulations of the Institution contained in those Articles of Association, but was merely intended as a suggestion, and therefore he thought it might properly be brought forward, after notice, at an ordinary general meeting; but he was afraid it was beyond the power of that meeting to entertain it.

Prof. J. PERRY said the difficulty was that when the resolution was brought forward an idea was given that it might be brought forward either as a resolution or as an amendment. Until the scrutineers had spoken he was still a member of the Council, and he had seconded the resolution for the adoption of the Report; but, in all fairness, he thought it was within Mr. Raworth's right to have this matter considered either as an amendment or as a resolution.

The PRESIDENT said it was a very simple matter. They all wanted the same thing. Mr. Raworth and the gentlemen he represented wished to have this motion brought forward. They (the Council), as in duty bound, asked their honorary solicitor as to what was the best course to pursue, and what was the legal course to pursue. He informed them that the legal course would be that the matter should be brought forward after due notice at an ordinary meeting. What was the use of ignoring the law on the subject and flying in the face of skilled advice? He thought Mr. Raworth's object would be best met by giving notice, and having the matter discussed at a future meeting.

Mr. A. E. MAVOR asked if the honorary solicitor would state whether it would be distinctly illegal to discuss the matter at that meeting. As he understood the object of the meeting, it was to discuss the state of the Institution, and if this did not refer to the state of the Institution he did not know what did.

Digitized by Google

Mr. G. L. BRISTOW said the purpose of the meeting was to deal with the Report of the Council. Therefore any resolution come to should have some reference to what was mentioned in the Report. If Mr. Raworth wished his remarks to be taken merely as an expression of opinion, and if other gentlemen wished to express an opinion, he did not think it would be particularly out of order. But he thought it would be out of order to pass a resolution at that meeting. Perhaps the Chairman, in his discretion, if time permitted, would allow the discussion to go on.

Mr. RAWORTH said he felt they had rather got him in a trap. The President asked him whether he was going to submit his motion either as an amendment or as a resolution. He had a strong objection to carrying an amendment on the Report, because that would have the force of a vote of censure on the Council, and would be an extremely unpleasant thing to do; he had been extremely glad to be able to take up the attitude of offering to put it in the form of a separate resolution after the Report had been passed. He did not accuse the Council of having got the information first and then run the solicitor's opinion off on him afterwards, but the effect was the same. He felt that to go on with this matter now would be to place himself in a very false position.

The PRESIDENT said if Mr. Raworth had been trapped it was accidentally. He (the President) was not aware of what would be the effect of what he said; they were advised afterwards, and he did not know what the effect was going to be. He had no wish to take an unfair advantage, but it had seemed inconvenient to discuss the thing partially then and to take it up again afterwards. If the question was one of supreme interest, it might be better to deal with it at once, but he did not think this was a matter of supreme interest. They would get quite as large a meeting to discuss the proposition in the early part of next year, and he was quite ready to put it to the meeting whether they should go on now, or whether they should discuss it later.

Mr. RAWORTH said if they could not take a vote upon it he did not think it would be doing any good to go on with the discussion.

Mr. HANDCOCK said this was decidedly an important matter, and one which could scarcely be decided at one time. It was as well that it should be discussed at once, and that they might consider it in the meantime before it was finally settled. They had to confess that the members, as a whole, were not in touch with the Council, and *vice versâ*. Their intentions were good, but they remained on parallel lines and did not come together. It seemed to him if they started by appointing a Committee to advise the Council, the next step would be to appoint a Committee to advise that Committee. They had better take a few hints from the Civil Engineers. He thought the Institution was working on the right lines in having on the Council the past presidents, whose experience was invaluable; but at the same time, if they were to have voting power in such numbers as to be able to out-vote the purely elective members, there was the danger of their getting behind the times as an Institution. In electrical matters particularly they must go ahead, and he certainly thought it would be much better if it could be arranged that the past presidents could not vote; they would then have a greater number of names to choose from for the purpose of filling up the Council, and they would be bringing fresh blood more or less frequently into the Council. Under these circumstances the Council would more ably represent the ideas of the Institution as a whole. If it were possible to discuss this matter to-night, so that they might have something to think over, it would be better than having the matter sprung upon them and dealt with right off that night.

The PRESIDENT: Shall we discuss this matter to-night or not? I think those in favour of discussing have it.

Mr. R. S. ERSKINE said those gentlemen who thought it was only necessary to make a little alteration in the constitution of the Council had rather mistaken the meaning of Mr. Raworth's resolution and his reasons in bringing forward that resolution. There was a very great difficulty at present for any member to bring any suggestion before the Council. Of course, with individual members, knowledge of the feeling of the Institution was confined to his knowledge of his own personal friends, who necessarily formed but a small proportion of the whole list of members, and when the member had found that among his own friends a certain change was desired he could only, in an informal manner, approach some member of the Council whom he happened to know, and, as Mr. Raworth had very justly said, that member would naturally ask, "Whom do you represent?" Even if he could at that moment remember all those with whom he had discussed the matter, the individual member would only be able to, at the best, represent a very small clique. That that view should be taken by the Council was only natural. It certainly did seem to him that if a Committee were appointed, as Mr. Raworth suggested, that difficulty would entirely be got over. He didnot think it was possible on that evening or in any one evening to bring before the Council all the suggestions which different sections of the members would like to make with regard to the future, and it was highly desirable that there should be a Committee in touch with the members to bring before the Council from time to time the various points which might arise in that direction. There was another point which could not be lost sight of. The deliberations of the Council were necessarily private, and were held with closed doors. It was perfectly right that that should be the case. It might, however, often happen that the Committee would have to bring before the Council certain matters which they would not like to bring forward in that room at the ordinary general meetings, which were practically public meetings. With the Committee such points might be brought before the Council and discussed in the way in which any matter concerning the Institution was at present discussed by that body.

Mr. J. N. SHOOLBRED suggested that the secretary should ascertain what was done by the various learned societies in London in the matter of the voting power of past presidents.

Mr. A. E. MAVOR said they were not entitled to quite so much congratulation as they were inclined to give themselves upon the accession of members to the Institution, for it was astonishing what a number of active and energetic members of the profession did not belong to the Institution. This was certainly due to the fact that the large proportion of the members of the Council were completely or almost entirely out of touch with the members of the profession. He referred, of course, to the past presidents, whose very eminence took them away from those who most in the nature of things have the future of the Institution in their hands. The Council's intercourse with the members was in his experience of the most charming and useful nature; but in asking the Council to open their ears to the desires and requirements of the younger members of the Institution, he did not think they were asking anything which ought not to be considered. The only thing they insisted upon was that the Council should know them better. They knew many of the members of the Council very well indeed, but they desired to be known in return. He spoke for many young members of the profession with whom he was in close sympathy and touch. Mr. Raworth had referred to a deputation which waited on the Council, but he did not state that that deputation took with them the requisite documents, signed by the requisite number of members, to ask for a general meeting to be called to discuss this matter. He was strongly of opinion that they ought to be given more time so that they could really understand the meaning of their Articles of Association. He knew the value of legal advice, but something more valuable than that was to understand sufficient of the law to be able to do without a lawyer. The Articles should be put in plain, simple English, so that they could all understand them.

Mr. G. L. ADDENBROOKE said it seemed to him that the resolution was sprung on the meeting in a very peculiar manner. There was an obscure letter in the papers staing that a meeting had been held, which apparently claimed to actually represent the members of the Institution. As a simple member of the Institution he might say that he never heard anything about that meeting, and it seemed to him that those who attended it had taken a great deal upon themselves. He thought anything of that nature should be approached in the most judicial frame of mind. In another Society of a very democratic kind with which he was connected—the Royal Photographic Society—of which he had been a member for 15 years, he had served on the Council for seven years, and during that period the Society had gone through every phase of the movement they were now starting on in this Institution. The practice of referring to the Society on every question led to a serious addition to the expenses, and in the end the Council became more autocratic than ever. No doubt the Council was anxious to do all it could for the members, and if the members had only been content to proceed in the proper and legal manner by calling a meeting and giving the matter proper attention, they would all have come to the subject with their minds prepared and tempers calm, and probably a fruitful discussion would have resulted. But he would really put it to the meeting whether the discussion, so far, had conduced to the dignity of the Institution, or whether there was any use in continuing it.

Mr. R. S. ERSKINE suggested that a great improvement in the practice with regard to the issuing of the balloting-sheet would be for the names approved by the Council to be sent out six or seven weeks before the election took place. At present it was sent out seven or eight days only before the election, and there was absolutely no time for members to organise or do anything in the way of nominating someone other than those whose names were on the list.

Mr. A. A. C. SWINTON wished to support what had been said by Mr. Erskine. He did think this Institution wished to be guided by the example of a photographic society such as Mr. Addenbrooke had referred to. Let them rather be guided by the Institutions of Civil Engineers and of Mechanical Engineers. In the Mechanical Engineers he believed the practice which Mr. Erskine suggested should be adopted here was followed, in sending out the balloting papers some considerable time before the day of election. Under

the existing practice in the Institution of Electrical Engineers members had not time to find out anything about the candidates, and they either voted by return of post to get the matter off their minds, or they did not fill in the papers at all. In any case a week was quite insufficient for any action to be taken.

Mr. J. HARDIE M'LEAN said as a country member this was the first he had heard of this matter, and he quite agreed with those who had said they should have had some notice that it was to be brought up. He wanted to hear more about it.

The PRESIDENT said there was other business to come before the meeting, and there was only just time to finish it. He thought they understood that notice was to be given immediately for the ordinary meeting for the special purpose of discussing this matter to the fullest extent. He hoped sufficient time would be given, so that the country members could be made fully aware of the bearings of this really momentous question, which amounted to this: that the Council was to be supplemented by another body to help it and advise it. This would be decidedly a most radical change in the constitution of the Institution, and it required most carefully investigating and thinking out. He wished at once, on behalf of the Council, to say that it was not fair on the part of Mr. Raworth to bring this matter on the meeting that evening and then to suggest that the Council had not acted fairly in declaring his resolution one which could not be put without notice. The Council wished to have the whole thing, the discussion and the voting, kept together, that is to say, to take place on the same night. In that case one long evening might have been given up to it, and people would have come prepared, whereas on this occasion most of those present had come to hear a discussion on the two Papers read at the last meeting.

ANNUAL DINNER OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The annual dinner of the Institution of Electrical Engineers was held on Friday night at the Freemasons' Tavern, Great Queen-street, under the presidency of Mr. R. E. Crompton, upwards of 250 gentlemen being present. Amongst those present were the Duke of Cambridge, Lord Claud Hamilton, Sir F. Abel, Mr. W. H. Preece, Mr. Latimer Clark, Mr. J. Wolfe Barry (Vice-President of the Institution of Civil Engineers), Gen. Markham (Director-General of Artillery), Sir J. Crichton Browne (Treasurer, Royal Institution), Prof. D. E. Hughes, Sir T. Blomefield, Dr. A. G. Vernon Harcourt (President of the Chemical Society), Dr. John Hopkinson, Prof. W. E. Ayrton, Prof. S. P. Thompson, Capt. W. de W. Abney (President of the Physical Society), Major T. Cardew (Electrical Adviser of the Board of Trade), Sir Henry Mance and Prof. G. Forbes (Vice-Presidents). After the toast of "The Queen" had been honoured,

The PRESIDENT proposed "The Prince and Princess of Wales and the other members of the Royal Family." He did not know why they had never proposed at their dinners the toasts of the Army and Navy, but he could not help feeling that the presence of the Duke was in some way connected with those two professions of which Englishmen felt proud.

Mr. W. H. PREECE, in proposing "The Learned and Engineering Societies," said that the members of the learned societies were the masters of generalising and expressing laws, and engineers were adepts in the art of securing facts. The latter necessarily preceded the former, for they—engineers—succeeded by failing. Failure and success were necessarily sisters. They must in that room, where science and practice were invariably linked together, pay some homage to those great men who had placed science on that basis that they as practical men could handle it with ease and comfort. They could not forget that they lived in a country that had produced a Faraday, a Maxwell, and a Joule. Nor could they forget that they numbered amongst present scientists such names as Kelvin, Rayleigh, and J. J. Thomson. The weapons which scientific and practical men now used were observation and experiment, but the great distinguishing feature that the electricians had introduced into the world had been absolute and accurate measurements. It was by accurate measurement that the last and greatest discovery was produced, principally within the walls of the Royal Institution, where Lord Rayleigh had been able to detect in the atmosphere that which had eluded the observations of thousands of years—the mysterious argon.

Sir J. CRICHTON BROWNE said the toast which had been so felicitously proposed was, in these days of widespread and manifold culture and of highly specialised science, a very comprehensive one, and he was sure he could say that the learned societies of all sorts and sizes and denominations regarded the electrical engineers with intense interest and curiosity, with a lively sense of what they had already done for human advancement, and with keen expectancy as to what they were going to do next. The Royal Society the chief parent of all the learned societies, was of course charged with electricity in every pore, and was, indeed, one huge transformer. But skipping from its universality to the extreme conditions of specialism, and to that branch of medical practice with which he was mainly concerned, he would venture to assure them that these societies devoted to the consideration of mental and nervous diseases were compelled to watch them very closely, for it was unquestionable that they were increasing the bulk of the wear-and-tear diseases with which those societies had to deal. There could be no doubt that by their discoveries and their applications electrical engineers had made life more intense and hurried than it formerly was. He had no hesitation in affirming that the tripod upon which delusional insanity now rests was made up of theology, hypnotism, and electricity, representing respectively the spiritual, biological, and the physical aspects of man's nature; and not a day passed that he had not in his official capacity to listen to strange tales as to the iniquities of the telephone and the illicit employment of the electric light. But if electricity had swollen the tide of nervous diseases and tipped some of its breakers with foam, it had also brought compensations, for it had given them new and valuable means of treating disease, especially diseases of the spinal cord; and it had given increased facilities for securing the advice of eminent London physicians in cases of nervous disease in any part of the country—facilities of which, he regretted to say, the public still only too sparingly availed themselves. As regarded the Royal Institution, all he could tell them was this: that it was gradually sinking lower and lower—not in scientific standing, not in the number of its members, not in commercial success—but in temperature. It had sounded the depths of thermopometry, and it was inundated by copious and cooling streams of liquid air.

Mr. BARRY, after expressing regret that Sir Frederick Bramwell could not be present, said that what had been alluded to by Prof. Crichton Browne was less than the truth, that the future of electric engineering was immeasurable. Civil engineers, whether their business was to deal with the construction of bridges, railways, or docks, were under the deepest obligation to the electrical engineers. They found the use of electricity was more and more necessary and useful in every walk of the profession.

Sir FREDERICK ABEL proposed "The Visitors," coupling with it the name of the Duke of Cambridge.

The DUKE OF CAMBRIDGE said that in the presence of so many scientific gentlemen he felt rather at a loss as to the reason for his being called upon to be the spokesman for the guests. He had, however, perhaps one advantage, which was that through the position he had had the honour of filling for a number of years he had been able to judge for himself of the advantages given by science to that profession over which he had had the honour of presiding. He did not think that any profession had gained more by scientific progress in recent years than had the Army and the Navy. Those Services were now in a condition which no human being, when he himself began his career, would have thought it possible to attain within the period of one man's life, and yet, there he was, not altogether worn out—and he had seen these things, and was able to appreciate the extraordinary advancement of science, and the power it had given to the great professions to which he had alluded. He thought that slow and steady progress was common sense, and on that principle he had always endeavoured to act. Nobody could better appreciate the services that Institution had rendered to the Services by the advance of its particular objects; and he therefore proposed "The Institution of Electrical Engineers."

The PRESIDENT, in reply, said that when he was a young man he held this faith—that in seven days the world was made, and on the eighth was made a rifleman. Now he held the faith that on the eighth was made an electrical engineer. He believed they were the salt of the earth. He had not made that statement for years past without coming to believe it himself. He had not met in society so many friends who said, "Oh! you are an electrical engineer; that is interesting!" without coming to believe that they were doing something that was interesting. They were told that they were on the verge of an electrical age. Some in that room thought they were a little way on in the electrical age. But the public liked to say they were in their infancy. In one sense that was good hearing. There was no doubt that there was some truth in the assertion that as the last 40 years had been the age of steam, so probably the age to come would be the age of electricity. He thought that if invention stood still at the present time, that if they really only attempted to give the public the benefit of the inventions that already existed, that even now the age would be called the age of electricity. For it was now so perfected, and had come so largely into their lives that he was warranted in this assertion. But was there anyone in that room who did not believe that they could do much more? If there was anyone who did not believe that they could do as much in the next 20 years as they had in the past he was not fit to belong to them. They were taking into their ranks the best men of the age. Those who came before them—the great telegraphists; what had they done? It was hardly possible to go anywhere without finding an electric telegraph. The telephone was next in the field. What an enormous amelioration of life that was—or ought to be. He would say the same of the electric light, which had a great future before it. As regarded the future, he believed one thing. The age of steam depopulated the country, and sent the people to the towns. He believed the age of electricity would send them back. The means of communication would be so good that they would be able to work in the country, or, at all events, live in the country. They had only to look at what had been done in America by the vast mileage of electric tramways to realise great possibilities. There was no reason now why a man should not live 20 or 30 miles from his work, and instead of having constant anxiety as to catching trains, would simply jump into a tram passing his door.

The proceedings shortly afterwards terminated.

Argon.—The Académie des Sciences has awarded the Lecomte prize of 50,000fr. to Prof. Ramsay and Lord Rayleigh for their discovery of argon.

TELEPHONE COMPANIES' ASSESSMENTS.

On Monday a Special Sessions for South London was held at the Court House, Newington, before Col. Ross (Chairman) and other magistrates, to hear the appeal of the National Telephone Company against the rating placed on their property in three parishes in the South of London. Sir George Morrison represented the Telephone Company, and Mr. Horace Avory and Mr. Bassett Hopkins appeared on behalf of the Assessment Committee. The appeal was against the valuation lists of St. Mary, Newington; St. Saviour, Southwark; and St. George-the-Martyr, Southwark. The rateable value of the Company's property in St. Saviour's was placed at £368, in St. Mary's at £150, and in St. George-the-Martyr at £154. The mileage of wire in these parishes was 184, 75 and 71 respectively, and the annual rateable value had been arrived at by multiplying the number of miles in each case by three and two respectively.

Sir GEORGE MORRISON said he should not make any admission on any question of principle, because the case might have to be dealt with hereafter. In the ten years since 1885 the value of the Company's wires for rating purposes had been multiplied by eight. In 1885 the Company was put on a footing in some respects with the telegraphs. It was then rated at 5s. per mile of wire, which was increased in 1890 to 13s. 3d.—the average figure throughout the metropolis—and now it was placed, in the St. Saviour's Union, at no less than 40s. The Court of Appeal had decided that telephone wires were rateable, and he was, therefore, bound to admit that they were, though the case had not yet been taken to the House of Lords. Then arose the question as to the principle on which they were to be rated. He referred to the important case of the Attorney-General *v.* the Edison Telephone Company, which decided that a telephone was a telegraph within the meaning of the Telegraph Acts of 1863, 1868, and 1869, though the telephone was not invented or contemplated in 1869. The system of the National Company, however, was not "constant or fixed," nor had it been "purchased or acquired," as was necessary before he could claim that it should be rated as the telegraphs were. He quoted Mr. Castle's book on rating to show that the difficulty in the case of telephones lay in dividing the rateable value of the whole undertaking amongst the various parishes through which the wires passed. The parochial system of valuation was not altogether applicable to telephones, but some approximation to that might supply what they sought. The Company had 279,000,000 "calls" every year, but they could not tell what parish they came from, nor the earning capacity of a particular parish. He should not object to accept as a basis earning value of a wire per mile, or to take the net annual income of the Company, and divide it amongst the various parishes involved, according to mileage, if that could be done. He contended that batteries, instruments, &c., were chattels, and that their value should therefore be deducted from the property of the Company, before assessment, in the same manner as was allowed as regarded gas meters in the action Regina *v.* Lee. The total mileage of the National Company for the half-year ended June, 1895, was 126,238, and the total revenue for the same period £702,427. From this there had to be deducted £412,081 working expenses; £216,408 cost of reproduction of the 126,238 miles of wire at £12, calculated on a seven years' life all round; and £37,034 on account of "tenants' capital," which would leave £36,904. Deducting, again, rates at 6s. in the £ on £28,388—£8,516—they had £28,388. That produced a net rate per mile of 4s. 6d. The Company did not, however, offer to pay at that rate; but he was instructed to say that they were willing to pay on the basis of 30s., which, all things considered, he thought was fair.

Mr. G. BEAM, rating clerk to the National Company, said it was his duty to examine the assessments of the Company all over the country. He checked the assessments by dividing the rateable value by the number of miles, and if he considered the quotient represented the fair rateable value, he passed it for payment. So far as he knew, no method was employed in assessing. The bounds of an exchange district were fixed for the convenience of the Company and in accordance with the number of subscribers. A "call" consisted of calling up an exchange, and was not complete till the caller was put on with his correspondent. The Company did not enjoy a monopoly in their system, as was shown by the 19th clause of the licence they held from the Post Office. In order to ascertain the rateable value per mile, he divided the rateable value by the number of miles in the particular parish. Since January last he had no doubt the mileage in the St. Saviour's Union had increased. The new exchange in Marshalsea-road was opened for the convenience of the Company, and probably because the business had increased. Since 1892 the business in the metropolis had largely increased. In 1891 the total number of miles of wire of the Company was 39,497; now it was 126,238. He should think that the gross receipts in 1891 (£334,211), as given in a printed statement delivered by the Company in connection with a former appeal, was accurate; now the gross receipts were over £702,000. Roughly there was about one subscriber to every mile of wire, and they increased in about the same proportion as the mileage. He believed the Company was now paying 6 per cent. on some and 5 per cent. on other stock. The working expenses of £412,000 included operating expenses, salaries and general expenses and wayleaves, but not the Post Office royalties, which amounted to 10 per cent. of the gross receipts. The £702,000 was the gross earnings after deducting the Post Office royalties. The "tenants' capital" represented what capital a man would require supposing he took the system on lease. It would be required for switchboards, stores, &c., chiefly instruments. The total of the tenants' capital was £211,000. The earnings in the metropolis were larger than in the rest of the country, but he could not say that they were 60 per cent. greater. It had been stated by the Chairman of the Company that the average earnings per subscriber were £14. 14s. 5d. a year for the metropolis, and £9. 2s. 2d. over the whole United Kingdom. He knew the Company appealed in 1890 against their assessment, and that they withdrew the appeal on terms. The rating in 1892 was 28s., not 30s., as had been stated. £28,388 represented what the Company thought was the total rateable value of their property in the whole kingdom. The capital of the Company was over £4,000,000.

Mr. WALTER BARNET, surveyor, of Winchester House, said that, on behalf of the Telephone Company, he attended a meeting of the St. Saviour's Assessment Committee on October 16th, and asked the Committee on what principle they rated the Company at 40s. per mile of wire, but he did not get a satisfactory answer. The district, from a telephone point of view, was rather poor, and he suggested 30s. as a fair figure, but they declined to accept it. He should value a wire entirely in connection with what it earned. Much of the wire, such as junctions between exchanges, &c., was non-productive. The real way to rate the Company, though it would take a very long time to work out, was on the basis of a given loss or profit on its 279,000,000 messages.

Mr. AVORY, on behalf of the Assessment Committee, asserted that an appeal such as the present, involving an important question of principle—a statement which had been fully admitted by the other side—should not have been brought to this Court of Special Session. The Act of Parliament under which they were proceeding was passed to secure uniformity of rating in the metropolis, and for that purpose the Court of Special Assessment, to which such cases could be taken, was instituted. If this idea were not acted upon it was obvious that there would very likely be different decisions in different parts of London in regard to the same matter. Moreover, if the present appeal failed on figures, the Company would be able to appeal to the Assessment Sessions; but if it should succeed, the rating authority, on the other hand, would not have power to do that. His opponent having admitted liability to be rated, the only safe course for the Court was to compare the figures which formed the subject of appeal with the figures established by the quinquennial valuation of 1890. If an increase in the business had taken place the simple question would be, whether the rateable value had been increased in proportion to the increase of business. On this basis it could not be too much to increase the rating of 30s. in 1890 to 40s. now, because, while the business had admittedly increased over 50 per cent., the increase in the rating was only 33 per cent. He argued that the instruments, switchboards, &c., were rateable hereditaments, inasmuch as the wires would be useless without them, and if that contention were admitted he pointed out that the enormous sum allocated by Mr. Bean under this heading would be liable to be rated. As to this being a matter on which no decision had yet been recorded, he asserted that both the Recorder of Brighton and the Recorder of Manchester had decided it according to the view he presented. The suggestion seriously put before them was that the Company should only pay for the whole undertaking over the whole country on £28,388, although dividends of 6, 5, and 4 per cent. were paid on a capital of over four millions, and £70,000 a year was being put to the reserve fund. The contention was ridiculous. He therefore asked the magistrate to dismiss the appeal.

Mr. WILLIAM MARSHALL stated that he had had 20 years' experience of rating cases. In 1890 he valued the property of the National Telephone Company for the St. Saviour's Union. The rating of the Company then was 30s. per mile of wire. The increase in the mileage of wire in St. Saviour's Union would of itself justify a proportionate increase in the rateable value. In the present valuation he had put it at 40s., but in view of what he had learnt since then as to the earnings of the Company from the Chairman, and from witnesses, it ought to be increased to at least £5; in fact, the rateable value of the metropolitan portion of the Company's undertaking was £64,859, which worked out at £6 per mile as the rateable value. In St. Saviour's parish he made the receipts per mile come to £16 0s. 3d. He had estimated the rateable value of the wire in the Strand at £2 per mile, the same as in St. Saviour's. He did not know that in France telephone subscribers provided the instruments, the Company only providing the wires. The principle on which he should value the whole undertaking of the National Company was to take the total gross earnings in the whole area, subtracting the expenses, Post Office royalties, and wayleaves, which would give the net receipts to be divided between the hypothetical tenant and the landlord. Then, having regard to the little working capital that would be required, he thought 10 per cent. of the gross receipts was sufficient to allow the "tenant." Deducting that, they arrived at the annual value, plus rates, which were about 6s. in the £ in the metropolis. Reducing the sum by the amount of the rates they had the rateable value of the Company's entire undertaking, which would have to be apportioned over the various parishes covered by the undertaking.

Sir GEORGE MORRISON, in reply, addressed himself to one or two questions of law, and briefly reviewed the chief points of the Company's case.

The CHAIRMAN, after consultation with his colleagues, announced that the Bench had given the case their best consideration, and on the whole thought there was insufficient ground to disturb the finding of the Assessment Committee. They therefore dismissed the appeal.

Mr. AVORY asked that costs should follow the judgment, but the magistrates, having been addressed by Sir George Morrison on the point, held that several important points had been raised, and they declined to make the order.

Sir GEORGE MORRISON stated that, as the case applied to the whole of the United Kingdom, he should take time to consider the question of appeal.

LONDON COUNTY COUNCIL.

Electric Lighting in Places of Entertainment.

At the weekly meeting of the London County Council on Tuesday it was reported by the Theatres and Music Halls Committee that some time ago they instructed the engineer to inspect the electric lighting installations in all the places of public entertainment in London which were licensed by the Lord Chamberlain and the Council, and the inspection was now being carried out.

Bristol Electric Tramways.

It was reported by the Highways Committee that there had recently been established in Bristol a new system of electric traction upon tramways; and in view of the fact that they had continually before them questions relative to tramway undertakings of various kinds upon which they were called upon to advise the Council, they thought it desirable that they should view that new system in actual operation. They therefore proposed, if the Council approved, to visit Bristol for that purpose on a day to be fixed during the Christmas vacation, and they recommended accordingly.

Col. ROTTON said he would move that the recommendation be referred back. It was proposed that those gentlemen, who were not engineers, should go down and see the electric tramway in operation. What would they do? They would go down to Bristol, he had no doubt. They would be put into a tram and be paraded all through the town of Bristol as the London Committee come down to view that beautiful thing, and it would be an advertisement for that business altogether. But what would they learn? They would only learn that the tram was moved by an electric motor. What on earth had the Highways Committee to do with electric motion? His object in referring it back was that if it were necessary that information should be given to the Highways Committee on the matter of electric motive power, the proper course to adopt was to send down the chief engineer and so obtain the necessary information. The engineer would receive plans and everything it was necessary for the Committee to have.

Mr. BERESFORD HOPE said he would second the amendment. That was the climax of a very peculiar business altogether. It arose first of all by the engineer of the Bristol tramways inviting the members of the Committee personally to come down at his expense and examine the tramway. The Chairman of the Committee and certain members accepted that invitation. A saloon carriage was ordered to be ready at Paddington station to take the members of the Highways Committee down to Bristol at the engineer's expense. The next thing that happened he supposed was that the Chairman of the Committee took higher advice, and the result was that at the last moment a refusal was sent, and the poor engineer had to do the best he could with the Great Western Railway. He was bringing out those facts because he thought they threw a light on the whole thing, and that it was not a *bonâ fide* desire for information on the part of the Committee.

Mr. HUBBARD (Chairman of the Committee) said the whole of the particulars given by Mr. Beresford Hope were not in the report, but they would have no objection to placing them in the report. The members of the Committee were interested in the matter, and had a *bona fide* desire to learn all they could about the different forms of traction, and it was considered by the Committee, if they were going down to gather information which would be useful for the people of London, they had better ask the Council to pay their fares down. However, considering what had been said he thought he would consult the dignity of the Committee if he asked leave to withdraw the paragraph.

THE CHAIRMAN: The paragraph is withdrawn.

Horseless Vehicles—New Act.

It was further reported by the Highways Committee that it had been represented to them that the provisions of the Highways and Locomotives Acts practically prohibited the use in the public streets of light carriages driven by electric or other motors of any kind, those vehicles coming under the description of "locomotives," and that the restriction was likely to be a hardship in the near future upon inventors and makers of such vehicles. The late Government introduced a Bill last year to remove the restrictions on the use of vehicles under two tons in weight propelled by mechanical power, but the Bill was not proceeded with beyond the first reading. The committee were of opinion that in the public interest an effort should be made to obtain an amendment of the existing law in the direction indicated in the Bill referred to, and they recommended: "That the Parliamentary Committee be requested to approach the Government with a view to the re-introduction in the Session of 1896 of a Bill to amend the law with respect to the use of locomotives on Highways."

The recommendation was agreed to.

With regard to the intention of the Charing Cross and Strand Corporation to lay mains from the Charing Cross Bridge of the South Eastern Railway, across and along a part of the Victoria Embankment, &c., to the Corporation's station at Bull Inn Court, it was the opinion of the Highways Committee that the proposed route was not the best that might be chosen, and the engineer to the Council has been instructed to communicate with the Corporation with a view to the proposal being amended. With this object the Council formally disapproved of the proposed works.

VAUGHAN AND BROWN (LIMITED).—The Directors of this Company have declared an interim dividend for the six months ended September 30th last of 7 per cent. per annum on the Preference and 5 per cent. per annum on the Ordinary shares.

CORRESPONDENCE.

PRESSURES DANGEROUS TO LIFE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The question of the relative danger to life of the alternating and continuous currents is one which has been often discussed, and various beliefs have been expressed about it. The experimental data are scanty and conflicting, and a study of the reported accidents does not show any very great danger from alternating pressures below 1,000 volts. I cannot call to mind any fatal accident in England on any alternating-current network where the pressure has been 1,000 volts, and every *fiasco* which resulted from the early attempts at electrocutions in the United States points in the same direction. The pressures employed in those were about 1,200 volts.

Most of the fatal accidents in connection with electric lighting have been from arc-lighting circuits.

One case there is, reported by Dr. Biraud in his book "La Mort et les Accidents causés par les Courants Electriques," where death followed from contact with a circuit at 250 volts, alternating; but, so far as I know, the case is quite unique. The victim was very effectually earthed at the time, as he was holding in his hand a copper pipe. Death was instantaneous. No burns were observed. No examination of the body was made, and nothing is said of his age or state of health. On the other hand, there are numerous cases recorded of accidents from contacts with alternate circuits at much higher pressures without fatal consequences. Deaths certainly have occurred from continuous-current circuits at pressures below 1,000 volts. I remember one which happened in England about eighteen months or two years ago, where a man was killed in a mine by touching a conductor belonging to an electric haulage plant. The voltage was stated to have been 600, to the best of my recollection; but I am not able at the moment to find my notes of this case.

So far as I am aware, the case quoted above is the only one which supports the view that alternate currents are more dangerous to life than continuous. The muscular fixation which plays an important part in causing serious accidents is found with continuous currents as well as with alternating, as soon as the magnitude of current rises above a few milliamperes.

H. LEWIS JONES, M.D.

LEGAL INTELLIGENCE.

North Metropolitan Tramways Company v. The London County Council.

In the Appeal Court on Monday last, before the Master of the Rolls, Lord Herschell and Lord Justice Kay, the plaintiffs appealed from a decision of Mr. Justice Romer declaring that the Council could, under Section 43 of the 1870 Tramways Act, compulsorily purchase a portion of the Company's tramways without taking the whole of them. Under this section any local authority may, within six months after the expiry of a period of 21 years after the promoters were empowered to construct any tramway, give notice requiring such promoters to sell the undertaking, or so much of it as may be within the district controlled by the local authority. The North Metropolitan Tramways Company's tramways were authorised by three Acts, passed in 1869, 1870 and 1871 respectively. The County Council gave notice requiring the Company to sell so much of the lines as were authorised by the Act of 1871. The Company claimed that the Council were bound to purchase the whole of the Company's undertaking within the County of London at the same time, and, in support of this contention, pleaded the definition of "undertaking" contained in the 1871 Act, which defined the word to mean "the undertaking of the Company as authorised by the Acts of 1869, 1870, and that Act."

Mr. Cripps, Q.C., M.P., Mr. A. Carrington and F. C. Richardson appeared in support of the Appeal, while the Council were represented by Sir E. Clarke, Q.C., M.P., Mr. J. Fletcher Moulton, Q.C., and Mr. G. M. Freeman.

The MASTER OF THE ROLLS, in dismissing the appeal, said that there were two reasons why the appeal ought to fail. The first was the rule of construction that a private Act could not alter a previously-enacted public Act except by express words. Again, the word "undertaking" in Section 43 of the Tramways Act, as incorporated in the private Act of 1871, was to have the same meaning as in the incorporated Act "unless there was something in the subject or context repugnant to such construction." There was no repugnancy, for the definition of "undertaking" contended for by the Company would make nonsense of Section 43.

Digitized by Google

Lord HERSCHELL said that Section 22 of the Tramways Act provided that Section 43 should apply to every tramway subsequently authorised by Parliament, "save so far as it shall be expressly varied or excepted" by the Provisional Order or Act authorising the same. Therefore Section 43, with the meaning attached to the words used in it, applied to the Act of 1871. Mr. Cripps said that, because Section 43 was incorporated by the Act of 1871, the interpretation clause in that Act referred to Section 43 as applied to that Act. He relied on that as an express variation of the Tramways Act. But the interpretation clause alluded to commenced by laying down that the words of the Tramways Act were to have their old meaning, unless there was something in the context repugnant to such construction. Therefore, unless there was something that was repugnant, a new meaning could not be put on the words. There was nothing in this case to prevent the full operation of the word used in the Tramways Act, because "undertaking" was only defined in the private Act for the purposes of that Act. If the word "undertaking" in Section 43 were interpreted by the definition in Section 3 of the private Act it would be nonsense.

Lord Justice KAY delivered judgment to the same effect.

Boyes v. Wellington and Co.

In regard to this case, which was reported in our last issue, Mr. Storey, the expert who had been agreed upon to adjudicate in the matter, said he had tested the chuck in the presence of both parties. He found that the jaws that held the work down did not run true. The defendants' counsel, however, said it was obvious that the expert had not tested the chuck properly. Mr. Commissioner Kerr said he did not believe that. He must find for the plaintiff. The defendant, Mr. Wellington, said the chuck had not been properly mounted, which Mr. Storey denied. Mr. Commissioner Kerr said the defendants must refund the money. Judgment accordingly with costs.

Ritter v. Bolas.

This case was heard in the City of London Court yesterday. The plaintiffs, Messrs. Ritter and Puzey, the proprietors of the Cannon-street Hotel, E.C., sought to recover the sum of £7. 19s. for providing electrical power to the order of the defendants, Messrs. Bolas and Co., Ludgate-hill, E.C. The plaintiffs' case was that in July last their hotel was hired for the purpose of a ball which was given by a gentleman named Marks by way of celebrating his silver wedding. The defendants, hearing of the event, asked the plaintiffs to allow him to photograph the guests at the ball; and to enable the defendants to take the photographs they asked the plaintiffs to furnish them with electric current to supply a lamp with which the photographs were taken in a small room. Magnesium light was formerly used, but the electric light was now preferred and was much more generally adopted. The defendant promised to pay for the electric current used, but he had not done so. The defence was that the defendants went to photograph the guests at the plaintiffs' own request. The defendants never agreed to pay for the current. The plaintiffs agreed to supply it, and to accept a gratis set of photographs in return. The jury found for the plaintiffs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is in active preparation, and orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. The usual circulars, &c., are now being sent out. Full particulars post free on application.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper. price 6d.

TENDERS INVITED.—Particulars may be obtained at the Brazilian Consulate in London, Liverpool, Manchester or Glasgow of tenders required for lighting the city of Recife, Pernambuco, by electricity, which are invited by the Government of the State of Pernambuco, Brazil. Some particulars are given in our advertisement columns.

——— In reference to the above advertisement the following will be of interest:—Every tenderer must prove that he has deposited into the Brazilian State Exchequer the sum of $15,000 (15 contos of reis) in gold or in certificates of the Brazilian National Debt. This sum is to be returned to unsuccessful tenderers, and the successful tenderer will then have to double the amount of his guarantee deposit, which sum must remain in the State Exchequer until after the expiration of the term for which the concession for electric lighting may have been granted, and, should any portion of this amount be deducted in payment of fines imposed under the contract, the portion so deducted must be made good within eight days of the deduction. In addition to those less specifically set out, fines varying from $200 to $1,000 for breach of any clause of the contract or of any of the regulations drawn up by the superintending engineer are imposed. The Government appoints a fiscal engineer and other officials not exceeding eight in number, whose salaries and wages the contractor has to pay, and the contractor has, in addition, to supply the superintendent's office with a set of instruments and apparatus for testing, &c., at a cost not exceeding $10,000. The maximum term for the whole of the work under the contract is not to exceed two years, and the work has to be commenced within three months of the signing of the contract. Many of the clauses of the contract are very stringent, and those articles dealing with the vested interests of Messrs. Fielden Brothers, who represent the existing gas company in the city, require careful consideration. Under Article 16 provision is made for the possible adoption of a dual system of lighting—electricity and gas. The installation, which is of considerable size, should receive careful attention from British contracting firms.

——— The Guardians of St. Luke, Chelsea, require tenders for the fitting up of an electrical wiring installation, including fittings, in the Chelsea Infirmary extension, Cale-street, Chelsea. Tenders by noon, December 31st.

——— The Corporation of Durban invite tenders for the supply, and for delivery and fixing at Durban, of steam and electrical plant (high-speed steam engines, dynamos, cables, arc and other lamps, accumulators, &c.). Tenders to Messrs. Webster, Steel and Co. (agents to the Corporation), 5, East India-avenue, London, E.C., by the 28th inst.

——— The General Consul of the South African Republic invites tenders for the delivery of 5,000kg. 2mm. hard drawn copper wire for the Telegraph Department of the Republic. Conditions, &c., from Messrs. Belinfante Bros., Paveljoensgracht, The Hague, and tenders must be sent in to the Consul, at the American Hotel, Leidsche Plein, Amsterdam, by December 20th.

——— Messrs. Arnott and Co. (Limited) invite tenders for an electric light and power installation at their new premises in Henry and Princes-streets, Dublin. Tenders by 8th prox.

——— The Saltash Town Council require tenders for lighting the public lamps of the borough by electricity, gas, or otherwise. Tenders by 20th inst.

——— Tenders are invited for the electric lighting of Brumath-i-Els., Germany. Steam power is to be used. Conditions, &c., from the Bürgermeister.

——— Tenders are invited by the municipal authorities of Langué for the concession for the electric lighting of the streets. Tenders to La Mairie, Langué (Haute Loire), France, by the 31st inst.

——— The Municipal Council of Stuttgart are inviting tenders for the electric lighting of the Jakob and Bürger Schools. Tenders to the Städtisches Hochbauamt, Stuttgart.

Digitized by Google

TENDERS ACCEPTED.—At their last sitting the Llandrindod Wells Council considered the tenders received for the public lighting of the district. Mr. S. Jevons, of Birmingham, offered to light the streets electrically for £157. 10s. per annum, and proposed the use of 70 32 c.p. incandescents for the purpose. The Council also received a tender from a gas company, but decided by 30 votes to 14 to accept Mr. Jevons' offer.

——— The Harrogate Town Council have accepted the amended tender of the Southgate Engineering Company (Limited) for the supply of a 10-ton overhead traveller for their electricity works.

——— The Newport Free Library Committee have accepted the tender of Messrs. Alger and Sons, of Newport, for wiring the building at the sum of £147.

——— The Executive Committee of the Cardiff Exhibition have accepted the tender of Messrs. Strode and Co. for the electric lighting of the Exhibition from April 1st to November 7, 1896, for the sum of £3,000. Messrs. Strode are to provide 150 arc and 500 incandescents for this sum.

SALES BY AUCTION.—Particulars will be found in our advertisement columns of a preliminary notice concerning the sale, by Messrs. Wheatley Kirk, Price and Goulty, of the entire contents of the Acton Hill Works, London, W., in *re* the failure of Ronald A. Scott (Limited).

APPOINTMENTS VACANT.—It will be seen by our advertisement columns that Messrs. Street and Co., 30, Cornhill, London, E.C., have as clients a leading manufacturing firm, who require an electrical engineer, thoroughly qualified to design installations and prepare estimates, to go abroad.

——— Particulars will also be found of the requirements of a leading firm of electrical engineers and contractors who require a manager for a new branch in Johannesburg.

——— The Gas Department of the County Borough of Salford require an assistant electrician for a central station on the high-pressure alternating current system. Salary £2 per week. Some further particulars are given in our advertisement columns, and applications should be sent to this office, addressed "The Publisher of *The Electrician*," Salisbury-court, Fleet-street, London.

DISSOLUTION OF PARTNERSHIP.—Notice is given that Messrs. F. D. J. George and Henry Waghorne, who are prettily described as "butchers and electric light engineers," of Cheltenham, have dissolved partnership. Debts by Mr. George.

——— The firm of Wake and Sanders, of Crosby-square, London, E.C., mica merchants and general commission agents, has been dissolved.

BUSINESS CHANGES.—We are asked to state that the firm trading as Parr, Gillies and Hornidge, at Haggerston, London, N.E., and Buckingham, will in future be changed to that of Gillies and Hornidge, Mr. Parr having ceased to be a member of the firm. The business will be carried on as hitherto, the sole partners being Thomas Gillies and Edward Hornidge. Debts of and owing to the firm of Parr, Gillies and Hornidge will be received and paid by the new firm.

LIQUIDATION.—At a meeting of the proprietors of the Electric Lighting and General Development Syndicate (Limited), on the 16th November, it was resolved to wind up the Syndicate voluntarily. This resolution was confirmed on the 7th instant, and Mr. A. E. Lott, 8, Bush-lane, Cannon-street, London, E.C., was appointed liquidator.

——— Meetings of the creditors and shareholders of the British Steam Generator and Refuse Utilisation Company, Limited (in liquidation) were held on Saturday last at the Bankruptcy Court, Carey-street, W.C., the Assistant Receiver (Mr. Winearls) presiding. The Company was formed in June, 1893, with a capital of £600,000, to acquire certain patents relating to refuse destruction furnaces and to a system in connection therewith for the generation of steam power and electric current at a cheap rate. It is asserted that the vendor was to receive £30,000 in cash, but it was stated at the meeting that he had only received £286, and that altogether only 210,590 £1 shares had been issued, no public subscription having been invited. The liabilities are estimated at £2,500, and the assets consist of three patents, some works at Halifax, and shares in the London Refuse Steam Generator and Electrical Power Corporation (Limited) to the extent of £100,000, held by creditors for cash advances. The Official Receiver was appointed liquidator, assisted by a committee of inspection.

——— The adjourned public examination of the directors of the New British Electrical Installation Contractors (Limited) was to have been resumed at the Worcester County Court on Tuesday last, but owing to the absence of one of the directors (Mr. Duce), the examination was adjourned to January 22nd.

BROOK HOSPITAL LIGHTING.—The order for the steam engines for the electric lighting of Brook Hospital, for the Metropolitan Asylums Board, has been given to Messrs. G. E. Belliss and Co., of Birmingham. Originally double-acting engines were limited to 200 revolutions, while single-acting were allowed to run as high as 470 revolutions. It speaks well for the Belliss double-acting engine that an exception has been made in its favour, and that it is to run at a speed specified for single-acting engines.

WARNING.—Mr. G. A. Nussbaum, representative in this country of La Société Industrielle des Téléphones, writes as follows :—

"In view of the numerous infringements of the Berthon transmitter, now sold in the market, will you kindly allow me to sound a friendly note of warning in the columns of *The Electrician*. I beg to state that the English patent is still in full force. Consequently, persons dealing in instruments of this kind not made by La Société Industrielle des Téléphones will render themselves liable to legal proceedings."

A POLE-FINDER.—The Berghansen pole-finder is not intended for use by such explorers as Dr. Nansen, but is suitable for finding which end of two cables, or which of two terminals, is positive and which is negative. The instrument, which is supplied by Mr. R. Simon, Zulla-road, Nottingham, in a handy little case, consists of two small parallel glass tubes almost completely filled with a colourless liquid. At the ends of the lower tube are two electrodes, connected to clamping terminals on the frame in which the tubes are mounted. On connecting these two terminals to the points to be tested, a bright rose colouration is developed on the negative electrode. Simply by shaking the instrument after disconnection, the colour will disappear. This pole-finder, which is compactly and strongly made, should prove useful to dynamo and battery tenders and other users of electric current.

CATALOGUE.—Messrs. Clarke, Chapman and Co. (Limited), of Gateshead-on-Tyne, have sent us an advance copy of their 1896 catalogue of electrical plant and apparatus made by the firm. In many respects this useful compilation is a work of art, as it contains several large half-tone illustrations of the Victoria Works and of some of the Company s principal plants. We notice particularly views of the ingenious system of under-hung electric travelling cranes for shipbuilding purposes, which were illustrated in our columns recently. Numerous tables of data in regard to steam engines, dynamos, &c., and a considerable amount of other information, are given, which should prove useful to intending purchasers and to consulting engineers.

ASHTON-UNDER-LYNE.—At the last meeting of the District Council it was decided to form a special Electric Lighting Committee for the purpose of carrying out the provisions of the Electric Lighting Order.

AUTOMATIC MACHINES FOR TELEGRAPH FORMS.—To check the excessive waste of telegraph forms the Post Office have been experimenting with various automatic machines for supplying forms one by one. These appliances have been used at the central telegraph office for some months, and it is now intended to introduce them at the chief provincial offices to test their usefulness. The machine consists simply of a wooden box fixed on to the wall, from which a telegraph form protrudes, and as fast as one is removed another takes its place. The contrivance is not unknown in connection with lavatory papers.

AYR.—At the last meeting of the Town Council, Bailie Ure moved that the question of the advisability of constructing tramways between Ayr and the outlying districts, the motive power to be electricity, be referred to a sub-committee of the Electric Lighting committee for consideration and report, and after a short discussion the motion was agreed to. It is stated that the official inauguration of the electric light works will take place either on January 9th or 10th next.

BALMORAL CASTLE.—£1,400 is to be spent in the electric lighting of a portion of the Queen's residence in Scotland, the waters of the Gelder being utilised for motive power purposes. The ball-room is to be first lighted.

BANGOR (IRELAND).—At a special meeting of the Town Commissioners on Monday Mr. Bowman moved that the Commissioners apply for a Provisional Order. An amendment that the cost of obtaining the Order be first ascertained was, however, eventually adopted.

BATH.—Mr. Robert Hammond has presented his report to the Lighting Committee of the Urban Sanitary Authority on the electric light question and as to the value of the City of Bath Electric Lighting and Engineering Company's undertaking. The subject is dealt with under three heads : (1) the desirability of the electricity works being in the hands of the Corporation ; (2) the system of generation and distribution best suited to the requirements of the city ; and (3) the advisability of the acquisition of the existing electric light works. He favours the view that the works should be in the hands of the Corporation, and in support of this contention states that (*a*) it is the universal experience that even in places where gas is cheap there is a sufficient number of private consumers to make electricity supply works pay ; (*b*) combined public and private electric lighting works are becoming general ; (*c*) where works have been laid down on a sound and economical basis they are proving

Digitized by Google

a financial success; (*d*) the tendency is for local authorities to lay down their own works, and in all cases to obtain powers to deal with both public and private lighting; (*e*) there is a great probability of the cost of generating current being reduced as business extends; (*f*) electricity works for private lighting in the hands of a local authority are likely to be more economically carried on than works laid down by a Company, and therefore ratepayers should obtain a cheaper supply; (*g*) statutory powers for the establishment of works for private lighting may prove of great value to the community, and should be vested in the local authority. As to the question of the system to be adopted, Mr. Hammond favours that at present employed by the City of Bath Company (high-tension alternating currents) as being the most suitable for the district. The report recommends the Corporation to purchase the existing undertaking. The space for extension at the present works is limited, but Mr. Hammond thinks that the idea of two separate stations should not be dismissed as impracticable, but they could not be worked as economically as one station. Mr. Hammond deals with the actual value of the Company's works, and he estimates the generating plant and works at £8,285, distributing plant £6,500, or a total of £14,785. This figure, however, excludes the value of the land on which the generating station is built. It would be necessary for the Corporation to make the following additions to the present plant: Generating machinery capable of supplying current to an additional 6,000 lights, £5,500; low tension network, £2,500; extension of mains, £2,500; arc lamps, posts, rectifiers, &c., £3,000; contingencies and engineer's fees, about £1,000. These figures, together with the sum required for the purchase of the works amount to £26,285. If, however, the Corporation could not come to terms with the Company, then they could lay down their own works, either at the Bathwick Mills, where the water power would prove a useful adjunct for working the day load, or at the destructor station. In conclusion, Mr. Hammond thinks that, with 10,000 lights already connected and a revenue of over £5,000 a year, a profit sufficient to cover the interest and sinking fund might be earned from the outset. If the acquisition of the works be accomplished, he also recommends the Committee to carefully consider the bold course already initiated by the Company of utilising the site to the full by laying down additional machinery. At their last meeting the City Council decided to proceed with their application for a Provisional Order.

Berlin Industrial Exhibition.—Special efforts are being made to attract English visitors to this Exhibition, many of the side shows being arranged with this object.

Bexhill.—Mr. R. Kersey and Viscount Cantelupe, on behalf of a local syndicate, recently gave the District Council notice of their intention to apply for a Provisional Electric Lighting Order. This notice was discussed at the last meeting of the Council, and it was decided to offer no objection to the application.

Birmingham.—At the meeting on Monday last of the Public Works Committee of the City Council, Councillor Wilson introduced a deputation from the committee formed to resist the proposed introduction of the overhead system of electric traction on the Nechells tramway route. Mr. A. Dickinson, engineer of the Central Tramways Company, was also present, and produced models of the cars and the trolley system, together with photographs of the system at work in Leeds and Hamburg. He also pointed out that in the method proposed to be adopted in Nechells, instead of the double line of posts with wires stretched across the streets, as in the towns named, there would only be a single line of posts, and in the narrower parts of the route the posts might be dispensed with altogether, and brackets, projecting from the sides of the houses, might be utilised to carry the wires. Referring to the alleged danger of the system, Mr. Dickinson stated that he was prepared to break one of the wires and hand it to any member of the deputation without his sustaining the slightest injury. The Tramway Company were losing about £2,000 a year on the horse cars and 'buses. The Company were willing to place overhead wires on the Nechells route for six months, and if at the end of that time the system was shown to be not satisfactory, they would undertake to remove them. Alderman Cook, the Chairman of the Committee, thought the Company's proposal was a very reasonable one, but they would take further time to consider the matter before presenting their report to the Council.

Bolton.—At the last meeting of the Gas and Electricity Committee of the Town Council the electrical engineer (Mr. J. H. Rider) was instructed to prepare a report and estimate of the cost of certain extensions to the plant at the electricity station. This step was rendered necessary by the continual and steady increase in the number of customers for current.

Bonsall (Derbyshire).—At the last meeting of the District Council the Clerk was instructed to ascertain the cost of erecting gas works, and, alternatively, of electricity works.

Bradford.—Many of the Corporations of our large towns are already in trouble over their electric lighting undertakings, but the trouble is a unique one. The demand for current is so large that it is found impossible to keep up with this demand, and the Gas and Electricity Committee of the Bradford Corporation have some real cause for anxiety in this respect, as the expected demand for Christmas will doubtless overtax the possible capacity of the electricity works. For some time past the Committee have been unable to satisfy the applicants for current, and a special effort will have to be made in made in order to keep the supply for Christmas up to anything like requirements. New customers, we understand, have very little chance of obtaining current.

Bray.—The Town Commissioners have decided to proceed with their application to the Board of Trade for a Provisional Order.

Bristol.—At the last meeting of the Electric Light Committee a very satisfactory report on the present position of the electric light undertaking of the Corporation was presented. The Committee have now 429 customers on their books, and 23,840 lamps have been connected up. As this represents almost the total capacity of the plant at the Temple Back generating station, it will be immediately necessary to put in additional machinery to cope with the increased demand for current. At the same sitting a number of fresh applications were received, but it was decided to proceed with only a portion of them.

Brixton (London).—An effective display of electric lighting has been prepared for the Christmas season at Electric-avenue, Brixton, which for many years has been brilliantly lighted electrically by Mr. Fyfe. On the present occasion about 80 Fyfe-Main 2,000 c.p. arcs are used, and a large number of Ediswan incandescents in foliated shades. The latter are suspended from green festoons which cross at intervals the entire length of the covered promenade. This exceptionally brilliant display is, we understand, remunerative as well as attractive. The shops in the avenue, with their extensive shows of Christmas goods and novelties, reap a large harvest from the vast number of visitors who are attracted by the illumination, which is quite gala-like in its picturesqueness.

Cardiff.—At the meeting of the Lighting and Electrical Committee of the Corporation on Tuesday a letter was read from the Secretary of the Cardiff Exhibition, stating that the Executive Council had considered the offer of the Lighting Committee to supply them with electric current, but they could not avail themselves of it, as the total cost would be greater than that of a separate installation. At the meeting of the Executive Committee of the Exhibition the Machinery Committee presented a report on the cost of illuminating Old Cardiff, the Art Section, and Rosebery Hall with gas, and lighting up the remainder of the Exhibition and grounds by electricity. The report stated that the entire work would entail an expenditure of over £4,000, and as this amount was considered to be too high, it was decided to form a special committee, with power to enter into the necessary arrangements for the effective lighting of the Exhibition buildings and grounds at a cost not exceeding £3,000. This Special Committee have decided that electric light is essential to the success of the Exhibition, and although the cost was necessarily somewhat higher than that of gas, Messrs. Strode and Co.'s tender for supplying 150 arc lights and 500 incandescents from April 1st to November 7th, 1896, for an inclusive charge of £3,000, should be accepted, the Exhibition Committee to supply steam, but the contractor to put down engines and dynamos and instal and maintain the lights. Messrs. Strode and Co. were granted the concession for supplying current to exhibitors on the condition that the authorities receive a proportion of the receipts in consideration of the steam power supplied by them.

Central London Railway.—The City Commissioners of Sewers had before them at their meeting on Tuesday last the report of the Streets Committee on the amended plans for the city station of the Central London Railway Company. The Committee recommended the Commissioners to approve the modified plans, and this was, after some discussion, agreed to. On the motion of Mr. Pannell the following rider, modifying the guarantor clause, was added to the report:—

"That the report be adopted and referred back to the Committee, and that the words 'that the amount so deposited as guarantee be released from time to time as the work proceeds, on certificates given by the engineer to the Company, and endorsed by the engineer to the Commission, so long as a substantial sum remains on deposit to ensure the due completion of the works."

Colwyn Bay.—At a special meeting of the District Council last week it was resolved to proceed with their application for a Provisional Order.

Coolgardie (W. Australia).—The telegraph operators and clerks at the Coolgardie, Kalgoorlie and Kanowna post and telegraph offices are evidently determined to have a share of the "finds" of gold in the district, and are stated to have sent an ultimatum demanding £200 per annum salary, 2s. per hour overtime, and three weeks annual leave, threatening to strike unless these conditions are accepted within 48 hours. The Premier's offer of an allowance of £30 per annum to the operators and clerks on the goldfields, and 2s. overtime in addition, has been accepted,

Digitized by Google

the threatened strike being thus averted. In other respects Coolgardie, which but a short time back was a comparatively uninhabited district, is being brought up to date. The Grand Hotel has been lighted electrically by Messrs. R. W. Thomson and Co., of High-street, Adelaide, the plant consisting of a Crossley's [illegible] H.P. oil engine, a Crompton dynamo, and 120 16 c.p. incandescents.

[illegible]NTRY.—The City Council have decided to wire the Public Library for the electric light.

COWES (ISLE OF WIGHT).—At the last meeting of the District Council the Water and Lighting Committee recommended that £10,000 be the maximum expenditure inserted in the Provisional Electric Lighting Order, and that the Order as drawn be approved. This recommendation was agreed to.

DEVONPORT.—The Electric Light Committee presented their report at the last sitting of the Town Council. The Committee recommend that a Provisional Order be applied for, and that a sum of £30,000 be borrowed for the purpose of carrying out its provisions. After some discussion the recommendations were agreed to.

DUBLIN.—The members of the Society of Cab and Car Owners in Dublin are much disturbed at the threatened additional competition likely to arise from the adoption of electricity by the local tramway companies, and the Corporation has received a deputation, who placed the Society's views on the subject before the members. Only poor comfort could be given by the councillors.

DUTIES ON TELEPHONIC MATERIAL.—The Russian Customs authorities have decided that connecting cords for telephones, made of copper wire and covered with fibrous substances, with metallic tags, are to be classed as compound parts of telephonic apparatus under Section 169 of the Russian Customs Tariff, and pay a duty of 8 roubles gold per foot.

EDINBURGH.—At the meeting of the Town Council on Tuesday last the Electric Light Committee recommended that steps be taken to carry out the recommendations of Prof. A. B. W. Kennedy as to the electric light extensions set out on p. 238 ot our last issue. Mr. Mackenzie moved the adoption of the Committees' report, and made a statement as to the present position of and expenditure on the electric light works. This statement was practically a *résumé* of Prof. Kennedy's report, supplemented by figures dealing with the capital account of the undertaking. The report was, after some discussion, unanimously adopted.——At their last meeting the Plans and Works Committee decided to recommend that the Tron Church and Register House clocks be lighted electrically. The Committee had also under consideration the question of adopting the electric light for the City Chambers and the Royal Exchange, and the City Superintendent has been instructed to prepare a report on the question for the next meeting.

ELECTRIC BOAT PROPELLER.—For those who go down to the river in small pleasure boats, there can be no method of electrical propulsion more handy than an apparatus which can be fitted on to the rudder sockets of an ordinary rowing boat. The battery is placed in a convenient spot in the boat, the ordinary rudder is lifted out, and the electric rudder hitched on, a motor, propeller and rudder being combined. It then only remains to couple the battery to the motor by a short piece of cable and a switch, when all is ready for a few hours' boating. There are several forms of electrical boat propeller of this kind, but the latest we have met with is one manufactured by the Portable Electric Boat Propeller Company, of New York. In this the motor is not submerged, but is carried on the rudder handle just over the stern, and it drives the screw by means of a flexible shaft carried in a tube.

ELECTRICITY IN PRINTING OFFICES.—A recent issue of the *Eastern Daily Press*, which is published at Norwich, calls attention to the introduction of electricity for driving the printing machines used in the production of the paper. The work has been carried out by Messrs. Laurence, Scott and Co., electric motors being attached to the Hoe rotary machines used in printing the paper. A remark is made that electric current has proved equally successful as a driving power and as an illuminant.

EXHIBITION.—We learn that an Electrical Exhibition, particularly for the display of electrical novelties, is to be held at the Agricultural Hall, London, in May, 1897.

EXPORTS OF TELEGRAPH WIRE AND APPARATUS.—The exports of telegraph wire and apparatus connected therewith from this country during last month is recorded at £70,459 against £39,769 in October, and £49,438 in November of last year. The returns for the eleven months ending with November show a total of £493,665, compared with £1,376,294 in the corresponding period of last year.

FAREHAM.—Many of the ratepayers of this town are taking their defeat by the local electric lighting company in anything but a kindly spirit. Having elected members to the District Council pledged to undo the action of the outgoing Local Board, with the almost inevitable result that she law would uphold the action of the droperly-constftuted local authorities, the ratepayers are at their wits ends to make the blow dealt in the law courts fall as lightly as possible upon their pockets. It is stated that, in anticipation of increased rates, rents have already been raised. A gentleman who took the chair at a recent meeting of the ratepayers mildly hinted that possibly the members of the District Council in cancelling the contract entered into by their predecessors, had not given due care and attention to the subject, and that, therefore, the consequences might fall upon the shoulders of the members of the Council. This gentleman finally put the whole matter in a nutshell by observing that—

"There were three questions for the ratepayers to take home and consider. First, did the District Council give due care and attention in cancelling a contract entered into by them and the Electric Light Company? Secondly, was it their opinion that it it was advisable that the town should purchase the business of the Company and not pay the damages, £3,800. Th rdly, was it their opinion that the town should not purchase the business but pay the damages, amounting to £3,800."

FOOTBALL BY THE ELECTRIC LIGHT.—An Association football match between the Old St. Stephen's and the Thames Ironworks and Shipbuilding Company's Clubs was played on Monday evening last, at Canning Town, with the aid of the electric light. As might have been expected, under these circumstances, the result was a victory for the Thames Ironworks Club by three goals to one.

GLASGOW.—Sir James Bell has just prepared his third annual review of the municipal trusts and other undertakings of the city. The report states that the additional capital expenditure during the year in the electric light department was £20,524. To meet the increased demand two new Babcock-Wilcox boilers, two 300 H.P. Willans engines, and two dynamos, each equal to 3,000 lamps of 8 c.p., had been brought into operation, while the extension of the mains to the West-end Park district had been completed. The private houses extending from the West-end of Park-terrace to Charing Cross can now be supplied with current, and during the year 28 houses have been connected, with a total of 3,930 lamps of 8 c.p. The aggregate number of consumers has increased from 488 to 725, and the number of 8 c.p. lamps wired from 59,543 to 68,550.

GRANGETOWN.—At the last meeting of the Eston District Council it was unanimously decided to form a committee to inquire into the cost of establishing electric light works at Grangetown. Councillor Dale suggested that the Council should borrow £4,000 at 3½ per cent. for the purpose. He said that £200 was at present being paid by the ratepayers for public lighting by gas which was of an indifferent quality.

HAMPSTEAD (LONDON).—The basis upon which electric meter rents have hitherto been charged having been found unsatisfactory, a new scale has been decided upon, varying from 2s. 6d. per quarter upwards. Further lighting mains have been put down in the district of Lancaster-road and Compayne-gardens.

HARROGATE.—Mr. W. J. B. Clerke held a local Government Board inquiry on Tuesday last into the application of the Town Council to borrow £27,000 for electric lightfng purposes. The consulting engineer, Mr. George Wilkinson, produced plans and gave details of the scheme, to which there was no opposition. The Council have fixed the price of electric current for private consumers at 6d. per unit.

HORNSEY (LONDON).—The District Council recently received proposals as to the electric lighting of the streets and buildings in the district, and the Lighting Committee, to whom the matter was referred, now recommend that these proposals be not entertained.

INDUSTRIAL EXHIBITION AT THE PEOPLE'S PALACE.—It is proposed, with the consent of the Governors, to hold an Exhibition at the People's Palace, to be opened in June, 1896, of the arts, trades, industries and handicrafts existing in the Eastern and other industrial districts of London, together with a general exhibition of the work of students in polytechnics and technical institutes. The former Exhibition of the kind, held in 1887, was visited by some quarter of a million of people. The financial results of the last Exhibition were, on the whole, very encouraging, as, out of a guarantee fund of £4,000 provided, it was only necessary to call up 10 per cent. It is desired in this instance to raise a guarantee of from £8,000 to £10,000, in order to increase the scope of the undertaking, and to distribute as widely as possible all liabilities in connection therewith. More than £6,000 has already been subscribed. It may be pointed out that in this, as in the former instance, those who subscribe to the donation or guarantee fund will do so without any intention or desire to reap any financial benefit, and that if any profits should accrue they will be devoted to social and educational purposes in East London. The proposed scheme may be, roughly speaking, described under five headings :—Section 1.—Open to exhibits of firms. Section 2.—Work of individual craftsmen. Section 3.—Work of students at the People's Palace and other polytechnics, technical institutions and public elementary schools of London generally, and of trade apprentices. Section 4.—An historical loan exhibition. Section 5.—A display of appliances and products bearing upon the social and

Digitized by Google

hygienic welfare of the population, supplemented by popular lectures on these and kindred subjects. The Committee appeal to all those interested in the encouragement of local industries, to employers of labour, and all others interested in the social and moral welfare of the industrial classes, to assist them in getting together the necessary guarantee fund. Donations are also invited towards current expenses.

KIDDERMINSTER.—The Town Council have instructed the Borough Surveyor to report upon the plans of the proposed electric tramway between Kidderminster and Stourport.

KING'S LYNN.—The Town Council at their last meeting ordered the corporate seal to be affixed to their petition to the Board of Trade for a Provisional Electric Lighting Order.

LAMBETH.—The gentlemen who attended the recent deputation to the Board of Trade on behalf of the Lambeth Vestry have reported that, in their view, it is unwise for anyone commencing electric lighting operations to do anything further until the whole question has been definitely settled by the Board of Trade and others concerned.

LLANDUDNO.—Some time ago the District Council received an application for permission to construct a system of tramways in this district, the motive power to be electricity, and a special meeting of the Council was held last week to consider the matter. In consequence of the recent adverse decision of the ratepayers, the Council decided not to further deal with the proposal.

LLANELLY.—Messrs. J. C. Howell (Limited) intend to proceed at once with the work of establishing an electricity station in this town. The scheme is estimated to entail an expenditure of £15,000.

LONDON, E.C.—If the extension scheme of the City and South London Railway Company receives the sanction of Parliament, the destruction of the ancient church of St. Mary Woolnoth, at the junction of Lombard and King William-streets, is inevitable, as it is proposed to erect a station on the site. A meeting is, however, to be held at the Mansion House early in the year to protest against the threatened demolition of the church, and it is probable that an influential effort will be made to compel the Company to select a less historic site for the proposed station.

MARYLEBONE (LONDON).—The report of the Special Committee of the Vestry recently appointed to consider the question of the adoption of an electric lighting scheme is practically complete, and will shortly be presented to the Vestry.

NEWINGTON (LONDON).—The Vestry have decided to proceed with their application to the Board of Trade for a Provisional Order, and also to oppose the application of the County of London and Brush Provincial Company for a similar order.

NEWMARKET.—At their last meeting the District Council had before them the request of the Newmarket Electric Light Company, for sanction to their application for a Provisional Order, but the matter was adjourned to the next sitting of the Council.

PLYMOUTH.—At a special meeting of the Town Council on Monday it was decided to proceed with the application for a Provisional Order for the construction of a system of tramways in the town. The Council intend to adopt electricity as the motive power.

POLICE.—The action brought by the Edison and Swan United Electric Light Company against Arthur Attride, Edward Ingold and George Cosgrave, for alleged fraudulent marking of incandescent lampholders, which, as stated in our last issue, was adjourned, was again called at the Clerkenwell Police Court, London, on Wednesday, and further adjourned.

PORT ELIZABETH (S. AFRICA).—At a recent meeting of the Harbour Board the resident engineer submitted a scheme for the electric lighting of the jetties, harbour, grounds and stores, and for the adoption of electricity as motive power for the cranes, at a cost of £4,000.

PORTSMOUTH.—There is a proposal on foot to light the Portsmouth Hospital by electricity. Specifications for carrying out an experimental installation will be discussed at the next meeting of the Hospital Committee. At the last meeting of the Town Council it was stated that the Camber Committee hrd decided to light the town quay and the Camber electrically.

SHOPPING BY TELEPHONE.—A Liverpool firm, Messrs. MacSymon and Co. (Limited), in order to meet the growing disposition for ordering goods by telephone, have arranged two separate telephonic installations each in the care of a separate attendant. The telephonic arrangements admit of the counting house and the managers of the various departments being communicated with by subscribers or other customers.

SHOREDITCH (LONDON).—At their last meeting the Vestry, on the recommendation of the Electric Lighting Committee, approved the specifications and plans of the generating station buildings and offices submitted by the engineers, Messrs. Kincaid, Waller and Manville, and ordered that advertisements be issued inviting tenders for the same.

SHREWSBURY.—The Directors of the Shropshire Electric Light and Power Company have, in consequence of the support already given and promised to the Company's undertaking, reduced the price of current from 8d. to 7d. per unit.

STAPLE HILL (BRISTOL).—The Parish Council have decided to oppose the application of the Great Western Electric Light and Power Company for a Provisional Order for the district.

STIRLING.—At a special meeting of the Police Commission on Monday last it was decided to approach the local gas company with a view to arranging terms for the purchase of the gas works. This course was opposed by Bailie Wingate and Mr. MacDiarmid, who maintained that the Commission should not take any action in the matter until they had disposed of their Provisional Electric Lighting Order.

STOCKTON-ON-TEES.—On the suggestion of Mr. Ford, the gas-works manager, the Corporation have appointed a deputation to visit three towns where the electric light is installed for the purpose of collecting information with a view to the adoption of an electric lighting scheme for Stockton.

THE PRICE OF CURRENT IN THE CITY OF LONDON.—At the last meeting of the Common Council Mr. Brooke Hitching inquired of the Chairman of the Commission of Sewers whether, in view of the high price of current—viz., 8d. per unit, against about 6d. or less in other metropolitan areas—the Commission had reserved to itself the right to purchase the City of London Electric Lighting Company's undertaking on equitable terms, or if not, what notice would be required for the establishment of a municipal electric supply. The Chairman (Mr. Gordon) replied that the purchase of the undertaking could not be accomplished for 21 years, as the Commission had granted an exclusive concession for public and private lighting to the Company for that period. The term would date from the completion of the Company's contract, when the Commissioners' engineer would give his certificate, and nothing could be done until that term had expired. The reason the contract had not been completed before was that the Commission had, up the present, been unable to determine the best mode of lighting the minor streets. He hoped, however, that that question would be settled in the course of the next few weeks. As to whether any other electric lighting company could come into the City in opposition, he was of opinion that no other company could compete. Mr. Alderman Bell, on the contrary, declared that, in his view, there was nothing to prevent another company from coming into the City and working in competition with the present one. Mr. C. T. Harris urged that, while the Commission of Sewers had given no exclusive right, it was bound to oppose any other company which entered into competition.

TUNBRIDGE WELLS.—In consequence of the satisfactory manner in which applications for electric current are being received, it has been decided by the Town Council to proceed at once with the work of enlarging the electricity station, and the Borough Surveyor has been instructed to prepare plans for an addition to the building, and instructions have also been given to obtain another boiler, engine and dynamo.

WAKEFIELD.—In reply to a question, Mr. Alderman Sherwood (Chairman of the Electric Light Committee) stated at the last meeting of the City Council that they could not proceed with their electric lighting scheme until the Sewerage Committee had selected a site for the new sewage works, as the sewerage and electric lighting works were to be a joint undertaking.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Froggatt's Electric Lighting Company (Limited).

An extraordinary general meeting of this Company was held on Monday at Winchester House, Old Broad-street, E.C., under the presidency of Mr. C. de Murrieta, to consider two resolutions for winding up the Company, and appointing Mr. W. P. Eldrid liquidator.

The SECRETARY (Mr. Arthur S. Hiley) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, the report of the Committee appointed to examine into the position and prospects of the Company, and the circular addressed to the shareholders, explains so fully the state of affairs that there remains little for me to add, except to express my regret and disappointment that, in consequence of the failure of our efforts to obtain further capital, it has become impossible to carry on the business of the Company, and this at a time when everything points to a promising future provided certain modifications in the working and administration are carried out. The history of the Company must be well known to you, so that I need not detain you with a recital of the difficulties with which we have had to contend—difficulties inherent to every pioneer enterprise. I will only say that we have earnestly laboured without reward in the interests of the Company, and have at least shown that the system adopted by the Company is well conceived, and, under happier circumstances, might still achieve success. But all the available funds being exhausted, and no response having been made to the proposal of issuing Preference shares, it has become necessay for us to call you together to sanction the winding up of the Company, which under the circumstances we feel is the best, and, indeed, the only course to pursue; and for this purpose we recommend that Mr. Eldrid, the auditor of the Company, be appointed, he being already acquainted with the working of the Company, and thus well qualified to judge of the best means of disposing of the assets, or, if it be possible, the manner by which a reconstruction may be effected. I therefore move: "That it has been proved to the satisfaction of the Company that it cannot by reason of its liabilities continue its business, and that it is advisable to wind up the same, and that the same be wound up accordingly."

Mr. FROGGATT seconded the motion.

Mr. PHILIP HALL enquired whether there was no way in which the Company could be amalgamated with one of the larger electric lighting companies of London. It was a very serious matter for the shareholders that, in the space of about 12 months, a Company like theirs should have to be wound up, or it might be said, go into bankruptcy. He hoped that something might be done to see whether they could not either reconstruct or sell their rights to a larger company with a greater capital, which would be more likely to make the enterprise a success.

The CHAIRMAN said it would be a very advisable measure to adopt if the Company could be reconstructed.

The SOLICITOR (Mr. W. L. Cooper) stated that one of the present difficulties was that two or three writs had been issued against them, and it was necessary to pass the resolution proposed in order to protect the assets of the Company. Efforts had been made with the object mentioned by the shareholder, and they were still being made, and it was hoped that the liquidator might be able to carry them to a successful issue. Unless, however, the step now proposed were taken, the assets would be dispersed by execution creditors.

The CHAIRMAN put the motion, and it was carried unanimously. He afterwards proposed—"That Mr. Walter Percy Eldrid, chartered account-

Digitized by Google

ant, of 11, Old Jewry-chambers, E.C., be appointed liquidator," and this was approved.

Mr. BAXTER expressed a hope that the liquidator would succeed in reconstructing the Company, and that the contracts entered into would be carried out.

Mr. FROGGATT stated that measures had been taken to prevent all contracts in progress suffering more than could be helped by the present proposals, and he did not think they would suffer in the future.

The proceedings then terminated.

Swan United Electric Light Company (Limited)—(In Liquidation.)

The final meeting of the shareholders of this Company was held on Tuesday, at the offices of the Company, to receive the Liquidator's accounts of the winding-up. Major S. Flood-Page presided.

The CHAIRMAN said they had met not really to bury the pioneer of electric enterprise, for it was not quite dead. Phœnix-like it rises from its ashes in the Edison and Swan United Company. Those present who could go back to the time of the inauguration of the Swan Company could realise what a very great work was done by it. It must be a gratification to them, as it was to all, to know that Mr. Swan, who began his investigations in connection with the electric light in the year 1845, was still among them, giving them invaluable aid and assistance in the work they still had to do. They had gentlemen present who took an active part in the formation of the old Swan Company, at a time when electric lamps cost 17s. 6d. each to make, and were what we should now consider to be of very poor quality. The best quality lamps were now being sold at 1s. 9d. each in the face of great competition.

The LIQUIDATOR (Mr. H. C. Gover) then presented his statement of the distribution of assets, and it was resolved: "That the accounts submitted be received and adopted, and the books and papers connected therewith be handed over to the Edison and Swan Company."

Mr. SWAN seconded the resolution, and said that it was always a melancholy thing to assist at a funeral, but the Chairman had been pleased to speak of its resurrection in the Edison and Swan United Company. The remarks of the Chairman had aroused in his recollection many interesting reminiscences during the vicissitudes of the old Swan Company, and he was glad that he had been able to assist in giving the people a more wholesome and better light than before. The changes of the companies which had taken place had not always been agreeable to him, but he had not opposed them because he had supposed them to be in the interest of the shareholders. In a number of instances he had suppressed his own feelings and his own interests in order that a better chance of success might be given to the Company. He believed that the Edison and Swan Company had a long and prosperous career before it.

The resolution was carried unanimously, and the proceedings terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRITISH ELECTROZONE CORPORATION (LIMITED).—This Company was registered on December 10th with a nominal capital of £250,000, in £5 shares, to carry into effect an agreement between John A. Barham and William Digby, and Frederick W. Manley (acting for the Company) to purchase, apply for, acquire, develop and work letters patent, patent rights, concessions, protective trade marks, designs and copyrights for the manufacture and application of Woolf's electrolysing, bleaching, and disinfecting process in the United Kingdom, and in any country except the United States and the Hawaiian Islands, and to carry on the business of manufacturers, merchants, contractors and engineers. The subscribers, with one share each, are: A. C. C. Codd, East India merchant; J. D. Jehu, G. Hazelgrove, A. J. Lusty, merchant; A. Riding, A. E. Griesbach, and E. H. Selby.

ELECTRIC AND GENERAL EXPLORING SYNDICATE (LIMITED).—This Company was registered on December 13th, with a capital of £5,000, in £1 shares, to acquire and deal in land, buildings, hereditaments, business concerns and undertakings, mortgages, charges, annuities, patents, licences, shares, stocks, securities, debentures, policies, book debts, claims, &c., and to carry on all kinds of agency business. There seems to be no particular "electric" business in connection with the Company.

NEW ELECTRIC LIGHT SYNDICATE (LIMITED).—This Company was registered on December 12th, with a capital of £2,000, in £1 shares, to effect an agreement between Bernhard F. de Morgenstern, experimental chemist, and Audley C. Miles (as the trustee for the Company) for the acquisition by the Company of a certain invention for the manufacture of electric current for light and power purposes, and to carry on the business of manufacturers of, and dealers in, electric batteries, lamps, switches, &c. The first subscribers, with one share each, are: C. V. Miles, Lieut.-Col. 1st Life Guards; Cecil Bingham, Captain 1st Life Guards; Audley C. Miles, Bernhard F. de Morgenstern, experimental chemist; J. G. Dalzell, Godfrey Pritchard, H. L. Mather. The first Directors are Audley C. Miles and Hon. Cecil Bingham.

NEWMARKET ELECTRIC LIGHT COMPANY (LIMITED).—The statutory return of this Company to November 2nd has been filed. The nominal capital is £30,000, in shares of £10 each; nine of these have been taken up, the full amount has been called, and £90 has been paid.

NEW-MAYNE ELECTRIC-RUDDER-MOTOR SYNDICATE (LIMITED).—The statutory return of this Company to July 29th was filed on December 2nd. The nominal capital is £20,000, in shares of £10 each; 879 of these have been taken up, and 807 issued as fully paid. The full amount has been called on six shares, and £8 per share on the remainder, resulting in the receipt of £588.

NEW PHONOPORE TELEPHONE COMPANY (LIMITED).—The statutory return of this Company to November 29th has been filed. The nominal capital is £10,000, divided into 9,000 Ordinary and 1,000 Founders' shares of £1 each; 5,031 of these have been subscribed for and allotted, a call of 10s. per share has been made, and £2,515. 10s. has been received.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 30⅜d. per oz. (Dec. 19th). Consols (2¾ per cent.) 106⅞—107 for money, 106¾—107 for account; 2½ per cent. 103⅞—104 (Dec. 19th). Stock Exchange Settling Days: Consols, Jan. 3rd; Stocks and Shares Continuation Day, Dec. 27th; Ticket Day, Dec. 28th; Pay Day, Dec. 30th. Mining Share Carry-over Day, Dec. 24th.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's Four per Cent. Mortgage Debentures, due on January 1st next, will be paid on and after that date at Parr's Banking Company and the Alliance Bank, Bartholomew-lane, London, E.C. Warrants in payment of these debentures will be sent out on the 31st inst. The register will be closed from the 27th to the 31st inst. inclusive.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The coupons on the second issue of Five per Cent. Debentures, due 31st inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, E.C. Coupons must be left three clear days for examination.

BRITISH NORTH BORNEO COMPANY (LIMITED).—At the general meeting of the shareholders of this Company, Mr. R. B. Martin, who presided, stated that the telegraph line had been completed to within 23 miles of Penungah, on the east coast section, and on the west coast section the line had been completed to Rayoh.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).— The transfer books of the Four and a-Half per Cent. Second Debenture Stock of this Company will be closed from the 18th inst. to January 4th inclusive, in view of the payment of the interest due on January 1st.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended December 15th were £1,014, against £962 for the corresponding week of 1894, an increase of £52. The total receipts for the half-year amount to £21,541, against £21,480 in the corresponding period of 1894, an increase of £61.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The transfer books of the £300,000 Five per Cent. Redeemable Debenture Stock of this Company will be closed from the 23rd to the 31st inst. inclusive for the purpose of preparing the warrants for the interest due January 1st next.

GUILDFORD ELECTRICITY SUPPLY COMPANY (LIMITED).—At the annual general meeting of this Company, held recently, Mr. A. F. Asher, who presided, explained that the Company, which was originally known as the Holloway Electricity Supply Company (Limited), had applied for a Provisional Order to light Guildford and district electrically. Notwithstanding the opposition of the local authorities, the Company had succeeded in obtaining an Order under very favourable terms. Sufficient capital had been already subscribed to justify the Directors in entering into a contract for the works, machinery, mains, &c., and in securing an excellent site for their station. They, however, required further capital to enable them to provide for an increase in the plant which would probably be shortly required. The Founders' shares, of which there are 500 of £1 each, and upon which no dividend is payable until the Ordinary shareholders have received 6 per cent. per annum, have been allotted to those who provided the necessary funds to meet the expenses of the formation of the Guildford Company.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 15th inst. amounted to £1,081. The amount for the corresponding week last year was £917, an increase of £164.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—This Company announces the payment by warrants, on January 1st next, of interest for the half-year ending December 31st on the Four and a-Half per Cent. First Mortgage Debenture Stock. The transfer books will be closed from the 18th to the 31st inst., inclusive.

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—The coupons on the Four per Cent. Guaranteed Debentures, due 31st inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, E.C. Coupons to be left three clear days for examination.

STOCK EXCHANGE NOTICES.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to, the City of London Electric Lighting Company (Limited) for the provisional certificates of the further issue of £100,000 Five per Cent. Debenture stock.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended December 13th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,895.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the half-month ended December 15th were £2,464, against £2,055 in the corresponding period of 1894. The August receipts, estimated at £3,226, realised £3,282.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 919. [Vol. No. 9. XXXVI.] FRIDAY, DECEMBER 27, 1895. PRICE SIXPENCE.

NOTES.

We would call the attention of those members of the electrical profession who take an active interest in the affairs of the Institution of Electrical Engineers to the letters on this subject which will be found in our "Correspondence" columns, and also to an article dealing with the methods of electing the Council adopted by the leading engineering societies of this country. A perusal of these documents will make it tolerably evident that the present mode of election at the Institution of Electrical Engineers is the least liberal of all, and the best calculated to lead to friction between the Council and the great body of members. As we have said before, the argument that although theoretically indefensible the system *works* well, cannot be put forward in this case. The question, which has been long simmering, having now been definitely raised, we trust not only that it will be discussed philosophically, but that it will be thoroughly threshed out and settled on a fairly permanent basis, to be heard of no more—during the present century.

Mr. J. W. Wilkins' letter on the earliest beginnings of public telegraphy, besides being highly interesting historically, illustrates another phase of the evolution of invention on which we have commented in our leading columns this week—the phase, namely, of one discovery helping another just in the nick of time to render it practically useful. The discovery of gutta-percha at the moment when the railway wires were standing still at the terminus, for want of an insulating covering, enabled the Telegraph Company to extend its system successfully underground into the heart of the City, and thus prove the practicability of adapting the telegraph to the wants of commercial and public life. Nature is often very generous; and we ought to be especially grateful to it for gutta-percha, seeing that it gave us a respite of nearly 40 years from the pest of overhead wires. Had Mr. Wilkins and company commenced operations in these days they would have carried their wires over the house-tops without waiting for the friendly gum, and we should have been—well, we shudder to think what the overhead system would have reduced us to by this time. By the way, that house in Seymour-street ought to be preserved as an historic relic—the first public telegraph office!

We publish this week an interesting set of Papers by Prof. J. C. Bose dealing with the subject of electromagnetic radiation. It was suggested some years ago in these columns, *apropos* of the "Eider," which, it will be remembered, ran ashore in a dense fog almost at the foot of the St. Catherine's light, that it would be a useful and a remunerative job for some practically-minded man to devise a practicable system of electromagnetic "light"-houses, the receivers on board ship being some electrical equivalent of the human eye. The evolution of a suitable generating apparatus would, we thought, present little difficulty; that of a suitable receiver, on the other hand, seemed likely to give considerable trouble. In this connection we would draw attention to the substantial and workmanlike form of "coherer" devised by Prof. Bose and described by him at the end of his Paper "On a New Electro-Polariscope." The sensibility and range of this type of "coherer" would appear to leave little to be desired, and it is certainly more likely to withstand with equanimity the thousand and one shocks that the flesh is heir to at sea than any of the forms hitherto brought out.

In our issue of October 18th we gave an abstract of a Paper by Klemencic on the development of heat in wires by electric oscillations. The "improvements" foreshadowed by the author have since been carried out by Prof. Cardani, whose Paper on the subject is abstracted in to-day's issue. It will be seen that Cardani has perfected the method and made it capable of accurately measuring the impedance of conductors conveying oscillating discharges. The definition of the "resistance" of a conductor is of considerable interest. "Two conductors offer equivalent resistances to a certain discharge from a condenser if, when placed successively in one of the branches of a divided circuit, the other remaining constant, they lead to the evolution of the same quantity of heat." The anomalous and unforeseen behaviour of very thin wires, especially platinum, iron and copper, deserves special attention.

A distinction of some utility is made by Dr. Borchers' in a recent Paper appearing in the *Zeitschrift für Elektrochemie*, between cases in which electro-metallurgical operations are best performed by means of the arc, and those more satisfactorily effected by the C^2R heat generated in a refractory conductor. When it is desired to prepare perfectly-fused masses of metals and their carbides or silicides, having extremely high melting points, the arc is extremely effective; when, on the other hand, it is sought to heat a considerable mass to a high, but not abnormally high, temperature, the

Digitized by Google

resistance method of heating is much to be preferred. The same material may even be susceptible of advantageous preparation by one or other method, according to its intended use. Thus calcium carbide, if made for immediate consumption in the production of acetylene, may be obtained sintered and not actually fused, by the resistance method of heating, and is then sufficiently porous to be rapidly acted upon by water. Should the carbide be destined for sale as such, and consequently required to be of compact character and easy of transport, the attainment of complete fusion by means of the arc suggests itself as suitable. It would be interesting to learn how far this view commends itself to those practically concerned in the manufacture of this new commodity.

It may be taken as generally conceded that the most hopeful field for utilising electrical energy in metallurgical operations is that in which the product is of sufficiently high price to warrant the employment of a comparatively costly method of heating. High-class crucible cast steel is such a product, and it has lately been proposed to prepare it in an electric furnace (of a continuous type) provided with a basic lining similar to that already freely employed for ordinary furnaces used in the manufacture of lower grades of steel and of ingot iron. Of course, in the case of the preparation of a fine cutlery steel the purest procurable raw material would be used, certain samples of spathic iron ore fulfilling this requirement. The roasted ore would be reduced with wood-charcoal in an electric furnace, and its content of carbon, if too low, corrected by the addition of spiegeleisen. According to a recent article in the *Zeitschrift für Elektrochemie*, the computed cost of the finished steel in bar, even when spiegeleisen has been requisite, is about £12. 10s. per ton, a price by no means excessive. The advantage accruing from the fact that the whole operation can be conducted in a neutral or slightly reducing atmosphere, and that it is practicable to maintain the temperature, at all stages of the process, at a point well above the melting point of the product, is not inconsiderable.

Fatality at the Frankfort Electric Lighting Station.—According to the daily papers Herr Sommer, the chief engineer of the municipal central station at Frankfort, has been killed by a 3,000-volt shock.

Cable Interruptions :—

	Date of Interruption.	Date of Repair.
Maranham-Para	December 18.	December 21.
Puerto Plata-Martinique	December 19.	—
Aden-Zanzibar	December 24.	—

King's College, London.—The Lent term of the engineering division, session 1895-96, commences on Thursday, January 16th. The electrical engineering course is under Dr. J. Hopkinson, President of the Institution for 1895. Some further information is given on another page.

Lightning Fatality.—A heavy thunderstorm suddenly broke over Brixham last week, but lasted only two minutes. Two flashes of lightning only were seen, one of which tore up the ground at Furzeham and struck a ropery. Four men were engaged in spinning rope ; one was killed and two injured.

Chicago "Times-Herald" Motor Cycle Race.—It is reported, by the *Electrical Review* of New York, that the $2,000 prize for the best horseless carriage in the *Times-Herald's* contest at Chicago has been awarded to Morris and Salom's "electrobat," on the grounds of absence of sound, vibration, heat and odour. The "electrobat" was equipped with chloride accumulators.

The Supply of Petroleum.—According to the *Gas World* the fall-off in the yield of petroleum in Pennsylvania has led to a good deal of searching for oil in other parts of North America. Los Angelos, California, has assumed prominence as an oil centre, and the Indian Territory has been found to be very rich in oil. It is believed that the basin of the Mackenzie River, 400 miles north of the Canadian Pacific Railway, will prove the richest oil region in the world.

Memorial to Mr. Denny Lane.—A public meeting has been held at Cork, under the auspices of the Mayor and distinguished patronage, to arrange for a memorial to the late Mr. Denny Lane. The meeting was called in accordance with a numerously-signed requisition. The form to be taken by the memorial has not yet been settled ; but the founding of a local scholarship at the School of Art seems the most probable. A subscription list has been opened, and has already been contributed to very extensively.

An Inquiry.—An esteemed correspondent writes us as follows :—"An owner of a cattle ranche in Canada writes that there is no sale for the hides of ranche cattle when slaughtered, on account of the brand burnt into the skin. The prices obtained for the beef have been lately so much reduced, that the value of the hide becomes of importance, and he is anxious to find some way of marking the animal which will not injure the skin. He has heard vaguely of some electrical process of permanently bleaching the hair in patches, and such a process, if it is practicable, might be very useful to him and others Would you be good enough to insert a note in your paper giving this statement, and asking any of your readers who know anything of this process to communicate with me (W. A. P.) through your office."

Patent Expiring.—To-morrow will expire Patent No. 5,702 of 1881, which was granted to Mr. J. W. Swan for "Improvements in Sockets or Holders for Electric Lamps." The claims attached to this patent are : (1) The employment of sockets or holders adapted to incandescent electric lamps without external fittings, and so arranged that efficient electrical contact is made and maintained between the hooks or their equivalents of the socket or holder and the lamp terminals by the outward push of a spring interposed between the lamp and the lamp socket or holder, or by the act of screwing or sliding towards the lamp an external tube substantially as hereinbefore described ; (2) The peculiar constructions, arrangements and combinations of parts constituting sockets or holders for electrical lamps substantially as hereinbefore described and illustrated.

Presentation.—Dr. R. Mullineaux Walmsley, late Professor of Physics and Electrical Engineering at the Heriot-Watt College, Edinburgh, who has been appointed Principal of the Northampton Institute, London, was on Friday, the 20th inst., the recipient of a handsome gift of books from his past and present students of the College. The presentation was made by Mr. C. A. Henderson, one of the day students, the chair being occupied by Principal Ogilvie, who warmly congratulated Prof. Walmsley upon his new appointment, and referred in glowing terms to the good work done by the retiring Professor and the cordial feeling at all times existing not only between the students and their teacher, but between Prof. Walmsley and other teachers in the college. Dr. Walmsley's departure was a great loss to them, but they could quite understand that the call to work in London was the only inducement that would have drawn Prof. Walmsley from Edinburgh, where his teaching work had been so very successful. Prof. Walmsley acknowledged the kindly sentiments expressed by the students and by Professor Ogilvie, and assured them that he would continue to take a great interest in all that concerned their future welfare.

Niagara Power and Buffalo.—On November 26th, says the *Electrical Engineer* of New York, the Buffalo aldermen unanimously reconsidered all action theretofore taken by that Board amending the Niagara Falls power franchise, and adopted the franchise by unanimous vote in practically the form in which it came from the joint committee, with the exception of the clause which fixed the percentage on the gross receipts at 5 per cent. As the franchise has now been adopted, the tax upon the gross receipts is fixed at 2½ per cent., and takes effect six years after the acceptance of the grant. The plans are to

Digitized by Google

be presented for approval by the Board of Public Works within 90 days after the acceptance of the grant, and the first 10,000 horse-power is to be ready for delivery to consumers within the city on or before June 1, 1897. The Power Company has indicated that it will accept the grant within the 30 days fixed for the acceptance by the franchise. The grant contains clauses for the ample protection of life and property, and while no maximum price is fixed for the power, as was at first insisted upon by the city authorities, there is a provision that the Company shall not charge any consumer a greater proportionate price or higher rate per horse-power than shall have been previously charged him.

The Plague of Modern Improvements.—Mr. Harry Furniss delivered himself of the following indictment in *The Times* of Friday last:—

"My experience in the last few weeks of the modern inventions which are designed to facilitate business and to benefit the public generally is, I think, worth recording, as I seriously question if these wonderful inventions and the extra expense incurred by adopting them are not a mistake. The working of the telephone has become, of course, a farce, and the sooner the Government take it up the better. Several large business houses have given it up, and London, which ought to be the most favoured, is probably the most unfortunate city in the working of the telephone of any in the world. I have tried half-a-dozen times in one day to ring up different people on the telephone without succeeding in getting through, and have had to send notes by hand. The electric light is another disappointing 'improvement.' Recently it has, in my own experience, gone out four times in one week, and we have had to use candles and lamps. Then there is the District Messengers' wire, which I have in communication with my house. I ring up for a cab; no response. I ring up again; nothing comes. I send out for a cab, and am late to dinner. The next day a representative calls casually to inform us that we cannot use the wire for two or three days, as something has gone wrong. I am now trying the phonograph; but, although at present I have had more correspondence about it than I have had through it I live in hope that I may find it worth the three years' trial the Company asks one to sign for. Altogether, it is a question whether paying rental for all these things, and then having, through their failure, to go to greater expense, is absolutely advantageous, and whether the story of the driver of the old stage coach who, when railways were introduced, remarked to a passenger, 'Well, all I can say is that if a coach comes to grief—well, there you are; but if there is an accident on the railway, where are you?' might not be very well applied to those experiments in the advancement of science intended to facilitate our work and add to our comfort. The electric light kills our sight; the telephone destroys our temper; the district messenger call ruins our dinner; and, conjointly, they waste our time and deplete our purses."

The Electrical Patents of 1894.—If we confine ourselves to the three countries, the United Kingdom, the United States, and Germany, says *Engineering*, we find that, in 1894, 3,315 patents more or less related to electricity were granted. What constitutes an electrical apparatus is not easily defined. The construction of underground conduits, the fixing of electric motors on cars, the casting of accumulator plates, the type-wheel trains of telegraphic instruments, switch plates for trolley wheels, have all a direct bearing upon electrical matters, though they may little concern the electrician. The 3,315 patents which we have classed as electrical are made up by 1,130 British, 1,704 United States, and 481 German patents. The 1,130 represent about $\frac{1}{20}$th of the total of the British patents for one year. The applications for British patents during the years 1893 and 1892 amounted to 25,102 and 24,166. The United States did not grant so many patents in 1894, only 19,874; Germany's contingent is, of course, considerably smaller, 6,279. There were altogether 365 improvements in dynamos and motors, armatures, field cores, and other accessories; and 450 patents concerning the distribution of electricity—apart from transmission of power—the connections of generators and motors, switchboards, leads, cables, their conduits, posts, insulation and insulating materials, safety fuses, rheostats, &c. Electric lighting, so far as not comprised in the two sections already mentioned, makes a special group of 395 patents. The electrical transmission of power introduces 460 more patents, a good many of which might, of course, just as well have been classed in the second section. Electric welding seems to have reached, or rather passed, its climax; the familiar names still predominate; in soldering, heating, &c., things have become more quiet. Electric devices for machinery in general, valves, stop motion contrivances, brakes, and electromagnetic clutches remain steady. The most ingenious, or, at any rate, most complicated automatic apparatus continue to be designed for selling cigars and giving electric shocks. This rather miscellaneous section, from metal working down to automatic apparatus, thermostats, ore separators (very few), and various mechanical applications of the current, contains 288 patents. Primary batteries come to 96, accumulators to 118. Commercial electrolysis, 158 patents, seems almost entirely to rely upon alkalis, bleaching, and chlorates, and what else is connected with the alkali industry. Two firms have new ideas about aluminium processes; electro-metallurgy, on the whole, is very poor, galvanoplastic processes not numerous either. In telephony and telegraphy matters are more lively again. We find 103 telegraph patents proper, 220 telephone patents, and 457 concerning railway and other signalling, police and fire telegraphy, telemeters and cognate instruments, bells, annunciators, &c. One well-known and able gentleman manages to condense his novelties in 127 claims, and has three other patents of the same title to follow. Electric meters of various descriptions, volt and ampere meters, counters, electricity meters furnish matter for 158 patents. Dynamometers are apparently perfect, as nobody bothers about improving them. Everybody has suddenly discovered, however, that one ought to be able to read current meters, &c,, from the side and from below. Two new photometers are offered. A good deal of what may euphemistically be styled electro-therapeutics might be passed over in silence. But there are a few useful suggestions among the 33 electric belts, special batteries, medical electrodes, and induction apparatus.

Contemporary Electrical Science.—The old problem of contact electricity has found another investigator in C. Christiansen, who gives a first instalment of his results in the current number of *Wiedemann's Annalen*. The method used was that of drop electrodes of mercury, the differences of potential being measured between the reservoir and metallic plates dipping into the mercury caught. It appears to have been very difficult to obtain consistent results, but the general tendency of the experiments went to show that the oxygen of the air plays a very considerable part in the electric phenomena. Thus, drop electrodes of zinc amalgam and of pure mercury gave rise to different potentials in air, but the difference vanished when the drops passed through hydrogen.—Ludwig Silberstein evolved a law governing the dielectric constants of mixtures out of his inner consciousness, and then set himself to prove it experimentally. Given two perfect dielectrics which mix perfectly without contraction of volume, and given their specific inductive capacities, what will be the result of mixing them? The law in question is that the new specific inductive capacities will be the sum of the products of the volumes into the specific inductive capacities, divided by the total volume. Silvertein succeeded in finding only two such substances for his test experiment: benzol and phenylethylacetate. The maximum deviation from the formula was 4 per cent., and the average 1·7 per cent. So this process of mathematical law-making may be considered a success. —G. Meyer contributes a laborious investigation into the differences of potential between metals and liquids in connection with the theory of the capillary electrometer, which, by the way, appears to be increasing its sphere of usefulness. Helmholtz's charge-current theory of this instrument is undermined, and the author's conduction-current theory is strengthened by the results obtained.—Another highly interesting portion of Paalzow and Neesen's Paper on "The Passage of Electricity through Gases" appears in the same number. Many curious facts were observed. On surrounding the discharge tube by different media, such as water, alcohol, or turpentine, the discharge is extinguished. This effect is not due to conduction, since the current is, if anything, enfeebled. On placing a point electrified by a Holtz machine near the tube, discharge was facilitated, and on moving the point all round the tube discharge took place even at atmospheric pressures.—K. Mack has continued his researches on the double refraction of electric rays. In the present Paper he repeats the experiments with rays of various wave-lengths, proves that the two rays are propagated with different velocities in wood, and describes the preparation of artificial anisotropic media, in the shape of modified Hertz gratings, or—more simply—piles of news. papers!—A Paper by Elster and Geitel, what may be termed a modified "Lenard" or cathode ray effect will be noticed later in more detail.

ELECTROMAGNETIC THEORY.—LXXX.*

BY OLIVER HEAVISIDE.

(*Continued from page 181.*)

§ 318. The case of a cable forming a closed circuit in itself without external constraint deserves some notice. Fourier's periodic theorem is involved, of course, but it has a somewhat different application to the one before made. If we have an infinitely long cable containing an infinite series of uniformly spaced point sources of equal size, we produce periodicity by symmetry. Every source produces a double wave, diffusing to the right and left respectively; and the effect produced at any point is the sum of the effects due to the individual sources.

But in the closed cable, in the corresponding case, there is one source only, and only two waves. The apparent multiplicity arises from overlapping. The matter is best understood by introducing self-induction to such a small extent as not to alter sensibly the shape of the waves, whilst making the speed of propagation be finite, say v. Then, if there is initially a charge Q at the point y, it splits into halves, and two diffusive waves result, one to the right and the other to the left, each containing $\frac{1}{2}$Q of electrification. The manner of this diffusion has been described before. The point here is that the two waves have fronts, which are at distance vt from the source, and which therefore rush round and round the cable in opposite directions. There is no reflection anywhere, so that the effect at any point x is the resultant of the overlapping of the right wave on itself, and of the left wave on itself. The potential at any point x makes a very little jump when either of the wave-fronts passes the place. There are two jumps in every interval of time equal to $2l/v$, the time of transit of a wave-front round the circuit. Between the jumps, the potential changes slowly (relatively) by the natural diffusive process. As time goes on, the jumps decrease infinitesimally, and the steady state is approximated to. This is $SV = Q/2l$, the mean value.

If we remove the self-induction, v becomes infinite. The initial waves therefore overlap instantly, and the little jumps disappear. We now have continuous variation of the potential, which is that due to the initial waves in reality, but with the proper allowance made for the overlapping.

The contrast with the behaviour in a distortionless circuit is striking. After the initial splitting, the two half-charges would go on travelling round and round at constant speed without any diffusion, though attenuating by leakage.

But keeping to the diffusion problem, the charge Q represents the result of an impulsive current pQ at y, which divides equally to the right and left. Therefore

$$c_1 = \epsilon^{-q(x-y)}\tfrac{1}{2}p\mathrm{Q}, \qquad v_1 = \epsilon^{-q(x-y)}\frac{\mathrm{R}p\mathrm{Q}}{2q}, \tag{33}$$

represent the current and potential at x, on the right of y, in the initial wave. To allow for overlapping, the factor for a circuital journey is ϵ^{-2ql}. That is, the second term in V_1 is $\epsilon^{-2ql}v_1$, the third is $\epsilon^{-4ql}v_1$, and so on. The total is

$$\mathrm{V}_1 = \frac{\epsilon^{-q(x-y)}}{1-\epsilon^{-2ql}}\frac{\mathrm{R}p\mathrm{Q}}{2q}, \tag{34}$$

representing V at x so far as the wave to the right is concerned.

Now, the same point x is distant $2l-x+y$ from y, when reckoned the other way round. Otherwise it is the same. So

$$\mathrm{V}_2 = \frac{\epsilon^{-q(2l-x+y)}}{1-\epsilon^{-2ql}}\frac{\mathrm{R}p\mathrm{Q}}{2q} \tag{35}$$

epresents V at x so far as the wave to the left is concerned. The complete potential V is V_1+V_2. That is,

$$\mathrm{V} = \frac{\cosh q(l-x+y)}{\sinh ql}\frac{\mathrm{R}p\mathrm{Q}}{2q} = \frac{\cos s(l-x+y)}{\sin sl}\frac{s\mathrm{Q}}{2\mathrm{S}}. \tag{36}$$

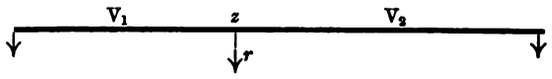
lgebrising this by the expansion theorem, we obtain

$$\mathrm{V} = \frac{\mathrm{Q}}{\mathrm{S}}\left\{\frac{1}{2l}+\frac{1}{l}\Sigma_1^\infty \cos\frac{n\pi}{l}(x\,.\,y)\,.\,\epsilon^{pt}\right\}, \tag{37}$$

where we recognise the unit impulsive function of Fourier's theorem, when we put $t=0$. There is only one such function now, instead of an infinite row; because x and $x\pm 2nl$ mean the *same* point.

§ 319. Passing now to a third minor matter, something should be said about the treatment of cases in which there are two or more connected Fourier series concerned. These cases can be constructed to any extent by means of intermediate conditions, and by combinations of cables. But a whole book would be required for a full treatment, and there are more interesting matters to be considered. So all that will be done here will be to take two or three cases of the kind, to be suggestive of what is necessary in other cases, and to exhibit matters of principle as well as practical working.

Say there is a leak at z. It may be any sort of leak, to be denoted by its resistance operator r. Let the



cable be earthed at $x=0$ and l.

There is one thing that can be done at once—viz., to write down the determinantal equation. For the sum of the currents leaving the point z is zero, and each current is the potential at z multiplied by the conductance operator of the path concerned. Therefore

$$0 = (\mathrm{Y}_1+\mathrm{Y}_2+\mathrm{Y}_3)\mathrm{V}_z \tag{38}$$

is the differential equation of the potential at z, where the three conductance operators are

$$\mathrm{Y}_1 = \frac{s}{\mathrm{R}}\cot sz, \quad \mathrm{Y}_2 = \frac{s}{\mathrm{R}}\cot s(l-z), \quad \mathrm{Y}_3 = \frac{1}{r}. \tag{39}$$

If there are terminal arrangements at $x=0$ and l, Y_1 and Y_2 must be suitably modified. It follows that

$$0 = \mathrm{Y}_1+\mathrm{Y}_2+\mathrm{Y}_3 \tag{40}$$

is the general differential equation of the complete combination satisfied by all subsidence solutions, and the values of p satisfying it, when regarded algebraically, are the values of p in the time function ϵ^{pt} of the normal systems. That is, the solutions are of the form $\Sigma a\epsilon^{pt}$, where the p's are known. But the a's are functions of x, and require further investigation.

The above process of finding the determinantal equation applies when any number of circuits of any kind meet at a point. But it is important to note that any point in the combination may be taken for origin. The difference may be very great in the form of the resulting equation, which may be simple at one place and complicated at another; but all the forms are intrinsically the same in containing a common factor whose vanishing determines the p's in the time functions.

Going further, consider the normal systems of potential. Let

$$\mathrm{V}_1 = \Sigma\mathrm{A}v, \qquad \mathrm{V}_2 = \Sigma\mathrm{A}w, \tag{41}$$

on the left and right of z. Here v and w are the normal functions. Since V vanishes at $x=0$ and l, we require

$$v = \sin sx, \qquad w = \mathrm{B}\sin s(l-x). \tag{42}$$

To find B, make continuity, or $v=w$ at z. Then

$$w = \sin sz\frac{\sin s(l-x)}{\sin s(l-z)}. \tag{43}$$

Two things remain—namely, s and A. To find s, we have the final condition

$$\mathrm{C}_1-\mathrm{C}_2 = \mathrm{V}/r \tag{44}$$

at z. Applying this to a normal system makes

$$\frac{\sin sz}{r} = -\frac{s}{\mathrm{R}}\left(\cos sz+\sin sz\frac{\cos s(l-z)}{\sin s(l-z)}\right), \tag{45}$$

or

$$\frac{\mathrm{R}}{rs}\sin sz+\frac{\sin sl}{\sin s(l-z)} = 0. \tag{46}$$

This is the determinantal equation, and is equivalent to (40) above, subject to (39), in a changed form.

Lastly, to find the A's to suit any initial state, this requires the construction of A in the case of a point charge. Say there is Q at y, less than z. Then, by the conjugate property,

$$A=\frac{Qv_y}{S\int_0^z v^2dx+S\int_z^l w^2dx+X}. \quad (47)$$

The numerator is the mutual energy of Q and the normal system, that is, Q multiplied by the potential of the normal system at Q. The denominator is twice the excess of the electric over the magnetic energy of the complete normal system itself. The part for the cable is explicitly shown. The part for the leak is denoted by X, to be found as before explained in special examples.

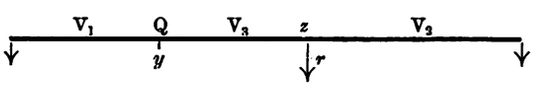
But X vanishes when r is a mere resistance. Then A becomes

$$A=\frac{(2Q/S)\sin sy}{z-\frac{\sin 2sz}{2s}+\left(\frac{\sin^2 sz}{\sin^2 s(l-z)}\right)\left(l-z-\frac{\sin 2s(l-z)}{2s}\right)}. \quad (48)$$

This completes the problem so far as any initial state of V from 0 to z is concerned, by an integration. But when Q is on the other side of z, we must use w_y instead of v_y in the numerator. Else it is the same.

§ 320. It will be seen that there is considerable facility in obtaining the normal systems, and also in evaluating A, provided that there is no allowance to be made for the leak itself, which may be a troublesome matter by the above process. But there is another way, whereby the evaluation of the energy difference is done by a differentiation without detailed examination of r. This will be explained presently. The same remarks about facility and the reservation apply in more complicated cases. But there is, nevertheless, a rather bad failing. We cannot, from the above normal systems, safely deduce the general operational solutions. If, on the other hand, we get the operational solutions first, we can at once deduce the Fourier series, and other sorts of solutions as well.

We may, therefore, now exhibit the more general way. Put a charge Q at y, and see the effect.



Start at $x=0$. First, we have

$$V_1=\sin sx\,.\,A, \quad (49)$$

satisfying the terminal condition. Next, as there is to be continuity in V at y, we require

$$V_3=V_1+\sin s(x-y)\,.\,B. \quad (50)$$

Here B is found by

$$C_3-C_1=pQ \quad (51)$$

at y, and makes

$$V_3=V_1+\sin s(x-y)\,.\,sQ/S. \quad (52)$$

Then there is to be continuity in V at z, so

$$V_2=V_3+\sin s(x-z)\,.\,D, \quad (53)$$

and $V_2=0$ at $x=l$ finds D, and makes

$$V_2=V_3-V_{3l}\frac{\sin s(x-z)}{\sin s(l-z)}, \quad (54)$$

where V_{3l} means V_3 at $x=l$. Finally, we have the discontinuity in the current at z, or

$$\frac{V_{3z}}{r}=-\frac{s}{R}\frac{V_{3l}}{\sin s(l-z)}. \quad (55)$$

This finds A definitely, and makes

$$V_1=-\sin sx\,\frac{\sin s(z-y)+\frac{sr}{R}\frac{\sin s(l-y)}{\sin s(l-z)}}{\sin sz+\frac{sr}{R}\frac{\sin sl}{\sin s(l-z)}}\frac{sQ}{S}. \quad (56)$$

This is the complete operational solution. Q is h/p, where h is an externally introduced source of current, which may in general be any function of the time. It is made impulsive specially to suit the treatment of an initial state.

As regards V_3, it is found by (52). It will usually differ from V_1, though not in the Fourier series solution for an initial state. It will be found that V_3 differs from V_1, comparing (52) with (56), merely in the interchange of x and y. Finally, we may use the modified V_3 in (54), and obtain

$$V_2=-\sin sy\,\frac{\frac{sr}{R}\frac{\sin s(l-x)}{\sin s(l-z)}}{\sin sz+\frac{sr}{R}\frac{\sin sl}{\sin s(l-z)}}\frac{sQ}{S}. \quad (57)$$

There are two distinct expansions, one for V_1 and V_3, the other for V_2. They follow from (56), (57), in the usual way, by the expansion theorem. But, denoting the common denominator $\sin sz+\ldots$ by D, so that $D=0$ is the determinantal equation, we can simplify the numerators by use of this relation. Then the expansion theorem makes

$$V_1 \text{ and } V_3=\Sigma\frac{-\frac{2Qs}{SR}\sin sx\sin sy}{\sin^2 sz\,\frac{d}{ds}\left(\frac{1}{r}+\frac{s}{R}\cot sz+\frac{s}{R}\cot s(l-z)\right)}. \quad (58)$$

Similarly for V_2. The form of the denominator was first changed in order to bring the relation (40) above into view. It may be verified that (58) agrees with (48) when the leak is a mere resistance. But (58) is far more general. The leak may be of any kind, r being a rational function of p, and therefore of s^2. When r is not a rational function of p, the expansion (58) fails. A definite integral is required. But the operational solution (56) remains true.

§ 321. The object of altering the form of the denominator of (57), so as to make the function in the big brackets in (58) be the active determinantal factor, as in (38), (40), was to introduce a point not noticed in the previous. According to (58), the value of the coefficient A is given by

$$A=\frac{Q\sin sy}{\sin^2 sz\times-\frac{RS}{2s}\frac{d}{ds}\left(\frac{1}{r}+\ldots\right)}. \quad (59)$$

This is the same as

$$A=\frac{Qv_y}{v_z^2\frac{dY_z}{dp}}, \quad (60)$$

if Y_z is the conductance operator at the point z, *i.e.*, the sum of the conductance operators of the three paths meeting there.

Now the general formula to find A from the conjugate property goes thus. Let there be selected any two normal systems, belonging to p_1 and p_2, say; let U_{12} be their mutual electric, and T_{12} their mutual magnetic energy. Then

$$U_{12}-T_{12}=0 \quad (61)$$

expresses the conjugate property. From which it follows that

$$A_1=\frac{U_{01}-T_{01}}{U_{11}-T_{11}} \quad (62)$$

is the coefficient for the term involving p_1; if U_{01} is the mutual electric, and T_{01} the mutual magnetic energy of the given initial state and the normal state in question, whilst U_{11} and T_{11} are double the electric and magnetic energy of the normal state itself.

The numerator in (60) agrees with (62), of course, because of the confinement of Q to a point, and because there is no mutual magnetic energy. There would be, if the initial state involved magnetic energy in the leak r. The denominator of (60), therefore, represents the denominator in (62). That is,

$$U_{11}-T_{11}=v_z^2\frac{dY_z}{dp_1} \quad (63)$$

for any normal system, which is here the first one. We need not use the suffixes, which may confuse, but, keeping to one normal system, write

$$U-T=v^2\frac{dY}{dp}, \quad (64)$$

understanding that Y is reckoned at the place of v. Now this property is general; z may be any point in the system v its potential there, and Y the corresponding conductance operator. The variations in v will be exactly compensated by those in Y.

Digitized by Google

To illustrate, divide Y into its three members; then

$$U-T=v^2\frac{d}{dp}(Y_1+Y_2+Y_3). \quad (65)$$

Here Y_1 is the ratio (conductance operator) c/v for the first path, Y_2 for the second, Y_3 for the third, all with the same v, but with different c's. And

$$v^2\frac{d}{dp}\frac{c}{v}=v\frac{dc}{dp}-c\frac{dv}{dp}=-c^2\frac{d}{dp}\frac{v}{c}. \quad (66)$$

We may therefore write

$$-(U-T)=c_1^2\frac{dZ_1}{dp}+c_2^2\frac{dZ_2}{dp}+c_3^2\frac{dZ_3}{dp}, \quad (67)$$

if Z_1, &c., are the resistance operators.

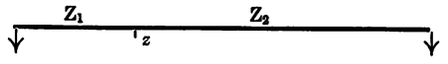
At the point z—that is, at the leak, there are three c's and Z's to be allowed for. But the last two c's may be expressed in terms of the first, bringing us to a result of the forms c_1^2dZ/dp.

If, however, any other point in the cable be taken, there are only two c's, two Y's, or two Z's, and the c's are equal. Then

$$-(U-T)=c^2\frac{dZ}{dp}, \quad (68)$$

where Z is the sum of the resistance operators to right and left of the point in question, which may be any point. dZ/dp is an inductance operator, and dY/dp a permittance operator.

It will be as well to illustrate these remarkable, though somewhat abstruse, properties explicitly. Take then the simple case of terminal earth connection and no intermediate



condition, so that the normal system is simply

$$v=\sin sx, \qquad c=-\frac{s}{R}\cos sx, \quad (69)$$

s having any value making $\sin sl=0$. Here

$$Z_1=\frac{R}{s}\tan sz, \qquad Z_2=\frac{R}{s}\tan s(l-z), \quad (70)$$

are the resistance operators to left and right of the point z, and their sum is

$$Z=\frac{R}{s}\frac{\sin sl}{\cos sz\cos s(l-z)}, \quad (71)$$

so that e/Z would be the current there due to e on the spot. Also $d/dp=-(RS/2s)d/ds$, since $RSp=-s^2$; so

$$\frac{dZ}{dp}=-\frac{R^2Sl}{2s^2}\frac{\cos sl}{\cos sz\cos s(l-z)}=-\frac{RSl}{2s}\frac{1}{\cos^2 sz}, \quad (72)$$

because $\sin sl=0$. Therefore

$$-c^2\frac{dZ}{dp}=\frac{s^2}{R^2}\frac{R^2Sl}{2s^2}=\frac{Sl}{2}. \quad (73)$$

Consequently, if there is initially Q at y, it expands to

$$V=\Sigma\frac{Q\sin sy\sin sx}{\frac{1}{2}Sl}, \quad (74)$$

which we know to be right. Of course the best place for z is at a terminal. Then only one resistance operator is concerned, and it goes simply.

Again, do it in terms of the conductance operators. Here

$$v^2\frac{dY}{dp}=\sin^2 sz\left\{-\frac{RS}{2s}\frac{d}{ds}\left(\frac{s}{R}\cot sz+\frac{s}{R}\cot s(l-z)\right)\right\}, \quad (75)$$

which also works out to the result $\frac{1}{2}Sl$, independent of the position of z. Here Y is the sum of the two conductance operators to left and right of z.

The practically useful point is this. If the evaluation of U – T by integration is troublesome, which is particularly the case when there is externally connected energy to be allowed for, we can avoid it altogether by means of the identity (64), choosing the point of reference so as to make the work as simple as possible. We do not, therefore, need to form the operational solutions and apply the expansion theorem, if the only object is to develop the proper Fourier series.

It may be objected in the above that in taking $v=\sin sx$, and assuming v to be potential, or the transverse voltage, we are violating dimensional properties. The objection is valid, though rather superficial. To be very particular, we may let $A\sin sx$ be the normal system of potential, A being the same as above, and so have a symbol to put the dimensions in (though they are not known, by the way). But this will make no difference in the end, and will complicate the formulæ somewhat. Or we may let $a\sin sx$ be the normal system, and let a be represented by a unit factor. For unity, though constant in a certain sense, may have any size and any dimensions.

A more important objection is that I have given no proof of the general properties used, except what may be contained in the actual verification in the examples used, which is sufficient as far as they are concerned. But the fact is, that the expansion theorem, and the conjugate property, and the equivalence of the integration and the differentiation ways of working it, being general matters, are best proved in a general manner, out of the general equations of dynamics, which, in their application to electromagnetics, will be considered separately.

(To be continued.)

THE GOVERNMENT OF NORWAY AND THE TELEPHONES.

BY ALFRED R. BENNETT.

Before the late Select Committee on the Telephone Service, it was stated that a committee appointed by the Government of Norway had reported in favour of State acquisition of telephones in that country. But the Government of Norway has, in fact, decided to do exactly the reverse; and the considerations which led to this decision are instructive. Telephone exchanges were first established in Norway, without any Government interference whatever, under concessions from the various town councils and local authorities in whose jurisdictions it was proposed to operate. But the Christiania Telephone Company very early in the day proposed to connect its system with that of the Drammen Company, by constructing a trunk line about 40 kilometres in length. The Post and Telegraph Department, fearing that the erection of such a trunk line would interfere with its income from telegrams, promoted a Bill conferring on the Government a monopoly in all inter-town telephonic lines. This became law on May 19, 1881; but the Telegraph Department, having got its way, did not proceed with the erection of any trunk lines, simply because it had no funds available for the purpose. It, therefore, arranged to license the various companies to connect their systems on payment to the State of an amount representing the estimated loss of traffic in telegrams. Matters so remained until 1892, when the companies and the subscribers, discovering that the sums paid to the Government as compensation exceeded the actual loss of income incurred by the Telegraph Department, protested against the continuance of the compensation payments, and petitioned for the abolition of all taxes on inter-town telephonic communication. This movement made itself felt in Parliament, and in December, 1892, the Government appointed a Committee to examine and report upon the whole telephone question. It must be noted that this Committee was not a Parliamentary or even an independent one, as, with the exception of two managers of telephone companies, it consisted of the Director-General of the Telegraph Department and several of his subordinates. The Committee was thus chiefly composed of State officials. In February, 1894, it presented a majority report in favour of the acquisition by the Government of all the telephone lines, local as well as trunk, but the minority reported in favour of the acquisition by the Government of the longer trunk and international lines only, leaving the local exchanges and shorter trunks in the hands of private companies and municipalities.

As soon as the majority report was published, protests were made by the various telephone companies, on the ground that the rapid development which had till then distinguished the Norwegian telephone system would be checked were the management placed in the hands of a central State autho-

Digitized by Google

rity in Christiania, inasmuch as such an authority would seek to make everything uniform throughout the country, ignoring local conditions and requirements, attention to which had been a most important factor in the success of the companies and municipalities. It was also feared that the Government would not be able to work so economically as the companies had done, and that it would be necessary to increase the rates of subscription. Colour was lent to this assumption by the proposal of the majority of the Committee to increase the local exchange subscription in Christiania, which for many years past had stood at £4. 8s. 11d., with most satisfactory results as regards dividend, 5½ per cent. having been paid uninterruptedly for many years, to £5. 11s. 1d. A meeting of representatives of the telephone companies and local authorities concerned was convened, and was held in Christiania on April 21, 1894. It was attended by 91 deputies, representing 48 companies and the Trondhjem municipality. Other companies sent protests against the majority report. The meeting, after discussion, adopted the following resolution: "The undersigned deputies from the greater number of the telephone companies in Norway submit that the exceptional development which the telephone has attained in Norway has been due to the manner in which the system has been hitherto managed and administered by local companies and authorities, and this meeting protests against the recommendations of the majority of the Committee appointed by the Government to consider the telephone question being carried into effect, and maintains that the best and cheapest method of working the telephone is that which has hitherto prevailed. With regard to trunk lines, the meeting considers that the question has not been sufficiently discussed, and it declines to pronounce an opinion as to whether the Government ought to undertake the working of the trunk lines; but should the Government resolve to acquire and work the trunk lines, then it is recommended that the present tax imposed on these connections be abolished."

In consequence of the strong public feeling displayed against the proposed State monopoly in telephones, the Government did not take any steps to bring the question before Parliament in 1894, but sent a circular to the municipalities and rural authorities, desiring an expression of their opinion on the subject. The reply to the circular was an almost unanimous expression of approval of the resolution adopted by the meeting of telephone representatives. The Government, thereupon, decided upon its policy, and during the session of Parliament of 1895 proposed, firstly, that the local telephone exchanges should remain as at present in the hands of municipalities, or of companies working under concessions from them; and secondly, that the inter-town trunk lines shall be acquired and worked by the Government. This proposal was adopted by Parliament practically unanimously.

The present position in Norway, therefore, is exactly the opposite to that which was suggested to the late Select Committee on the Telephone Service. Municipalities and local authorities have the right to establish their own telephone exchanges, or to license companies to establish exchanges, and this without any reference to Government, and without paying any royalty to the Post Office. On the other hand, the Government has acquired a monopoly in telephonic inter-town trunk lines.

The decision of the Government may possibly have been influenced by the fact that the telephone companies followed up their meeting in April, 1894, by forming a Telephone Union having for its objects the promotion of the telephonic industry throughout Norway by an interchange of views regarding extensions, tariffs, and technical and working arrangements. This Union held meetings in Christiania on January 28, 29 and 30, 1895, and, amongst other resolutions, determined to publish a fortnightly newspaper dealing with the telephone and electrical questions of general interest. Twenty-three numbers of this publication, the *Telefon-og-Telegraf Tidende*, have already appeared.

There is an institution in connection with the Post Office in Norway which might be copied in this country with advantage. The British system is to have a Postmaster-General who, previous to his appointment, has had no experience of postal, telegraphic or telephonic business, and who, nevertheless, is supposed to be responsible to the country for the conduct of the great Department of which he is the nominal head. Such an official, however experienced he may be in general matters, necessarily falls under the influence of the permanent officials of the Post Office, whom he naturally regards as best qualified by special training and long experience to guide him in matters appertaining to the Department. This course would be a logical one were it not for the fact that the Postmaster-General is appointed for the very purpose of controlling the permanent officials, and not for being controlled by them. The very *raison d'être* of such a functionary is the necessity recognised by Parliament of imposing some restrictions on the permanent officials, and the intention of Parliament is violated by the practical outcome of the present system, which has not infrequently degraded the House of Commons into an arena in which the Postmaster-General of the day has aired his ignorance of matters about which he was technically responsible to the nation.

They manage these things better in Norway. There the posts and telegraphs and such railways as belong to the State are under the immediate control of a standing Parliamentary Committee consisting of nine members, which Committee has power over expenditure and over contracts, and without its consent no modifications of existing regulations may come into force. The Postmaster-General and the Directors of the Telegraph and Railway Departments report to the Minister of Public Works when Parliament is not sitting, but during the Session they report direct to the House. But in any case their reports are referred to the Parliamentary Committee, and are digested by it before coming under the consideration of Parliament as a whole. This arrangement is found to work remarkably well, because the Committee is made up of members of Parliament who come from all parts of Norway and are acquainted with the needs of their several districts. Local requirements are not, therefore, neglected, as with us they are so apt to be, but receive careful consideration. As the members of the standing Committee usually remain on it for several years (as in the event of the dissolution of Parliament a proportion of them always returns to the new House) the Committee becomes well acquainted with postal, telegraphic and railway affairs, and constitutes a direct representation at these important State departments of the commercial interests of the country. Members of the Committee do not receive any salaries in return for their services.

Such a standing Committee of the British House of Commons would be well calculated to put so much life into our Posts and Telegraphs Department as would at least prevent reforms from being shelved indefinitely, or from only being adopted after the permanent officials have, so to speak, died in the last ditch in fighting against them. The responsibility to Parliament, which is now merely nominal, would then become actual and real, and the author is much mistaken if such a Committee would not find a very large field for useful explorations into the operations and methods of administration of the Post Office, which would not then, as now, be the master of the public instead of its servant.

THE DE LAVAL STEAM TURBINE.

At the present time there are in existence but three types of steam turbine of importance. Two of these are the parallel and radial-flow turbines, the invention of the Hon. C. A. Parsons (see *The Electrician*, Vol. XXXI., p. 315, and Vol. XXXV., p. 5), and the remaining one is the de Laval impulse or jet turbine. From a combination of several causes, the popularity of the steam turbine has been on the ascendant and seems likely to continue so. Its high and improving economy, its compactness, small weight, cheapness, and the absence of vibration, combine to make it a suitable motor for driving dynamos. The de Laval type is of more recent invention than those of Parsons; but the results of recent trials would seem to indicate that, though the de Laval engine can hold its own beside many modern steam engines, it is not yet quite equal to the Parsons engines in the matter of

Digitized by Google

economy. Before comparing the two makes of steam turbine, it may be useful to give some description of the newer one.

Fig. 1 shows at a glance the working parts of the de Laval turbine; these comprising the vanes, which are mounted on the periphery of a wheel, and the guide jets, in this instance four in number, which direct the steam at a very acute

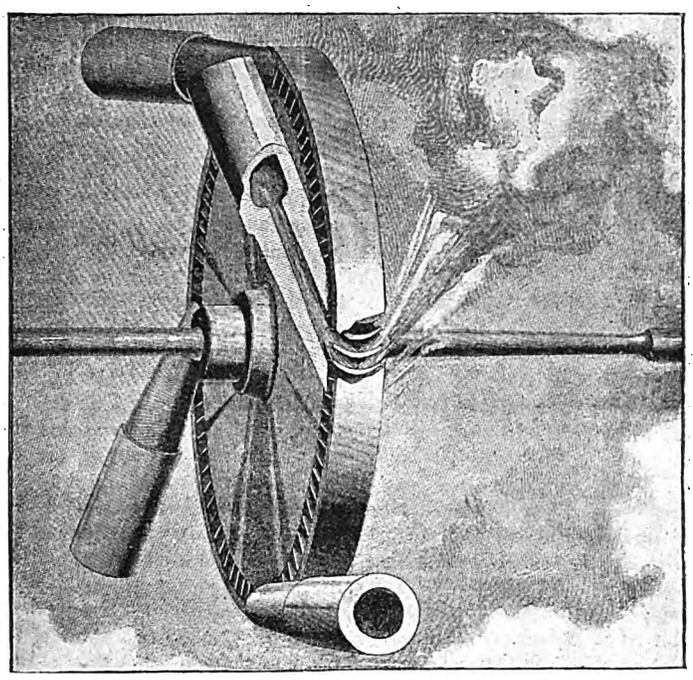


Fig 1.—Showing Action of Steam Jets on Vanes in the de Laval Steam Turbine.

entrance angle against the vane surfaces. The absolute path of the steam over these surfaces is, in any turbine, compounded of the motions of the steam and the vane; and the best conditions obtain only when the absolute velocity of the vane is half that of the entering steam, neglecting the small entrance angle. Accordingly the vanes are said to be run at a peripheral

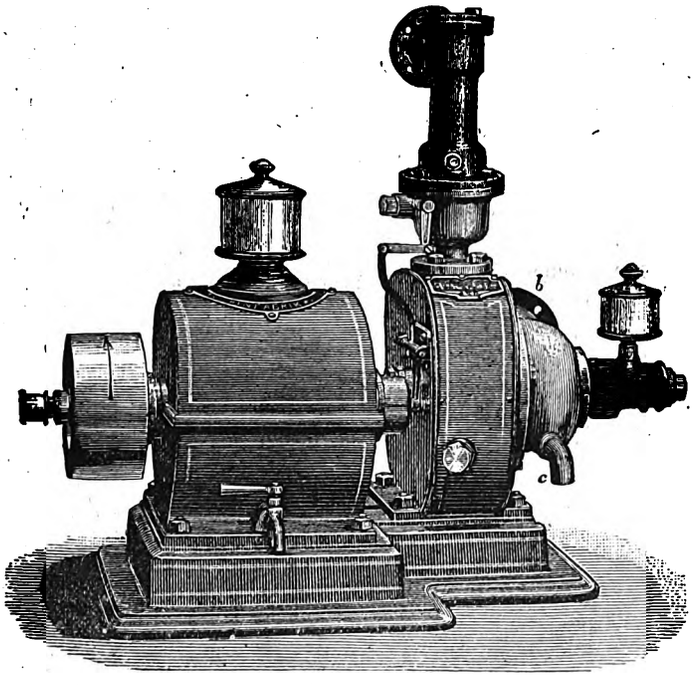

Fig 2.—De Laval Steam Turbine

speed of from 580ft. to 1,320ft. per second, these high speeds necessitating from 15,000 to 30,000 revolutions per minute.

Upon the spindle of the vane wheel are two pinions, with right and left-handed helical teeth respectively cut upon them. The pitch angle is 45deg., and the pinions engage in two large helical wheels, keyed to the pulley shaft of the motor. In this way any desired reduction of speed is obtained. The gear is contained in a separate casing, as shown in Fig. 2, and the use of oppositely-cut gears obviates the need for heavy thrust-blocks. In Fig. 2, which shows an external view of the de Laval turbine, the vanes and guide jets are contained in the narrower case to the right, and the gear in the wider case on the left, which stands somewhat further forward than the other. The following table gives the approximate sizes of the engine for various powers:—

Table I.—*Approximate Dimensions of de Laval Steam Turbines.*

H.P.	Length.	Width.	Height.
	Inches.	Inches.	Inches.
5	32·5	14·4	29·0
10	35·0	19·2	36·0
15	40·0	19·2	36·0
20	42·0	24·0	40·0
30	45·0	24·0	40·0
50	74·0	39·0	55·0
100	96·5	40·0	68·0

In July last, at the Bordeaux Exposition, some trials of this turbine were undertaken by the Philomathic Society. The engine used was rated at 100 H.P. normal load. Table II. shows the results obtained at full and half loads, and compares them with the economy of the Parsons steam turbine, as determined by Prof. A. B. W. Kennedy in 1893.

Table II.—*Steam Consumption of de Laval and Parsons Steam Turbines.*

——	De Laval.		Parsons.	
	Full load.	Half load	Full load.	Half load
Pounds per kilowatt-hour	32·23	40·26	27·9	29·3
Pounds per E.H.P. per hour	23·72	29·66	20·8	22·0
Pounds per B.H.P. per hour	20·15	23·80	—	—

In regard to the dynamo driven by the de Laval turbine, it has been assumed that the efficiency was 0·85 per cent. at ful load and 0·80 per cent. at half load.

A further source of information regarding the performance of the de Laval steam turbine is a Paper read this month by Mr. W. F. M. Goss before the American Society of Mechanical Engineers. The engine tested by Mr. Goss and Mr. G. E. Bruff was rated at 10 H.P. normal load. The belt pulley ran at between 2,000 and 2,500 revolutions per minute; and the reduction ratio of the engine gear was 9·905. Table III. gives a summary of the economy tests, which were made at various loads and with varying numbers of nozzles.

Table III

Nozzles.	Number of test.	Revolutions per minute of belt wheel.	Brake horse-power.	Steam pressure by gauge. In boiler.	Steam pressure by gauge. In engine below governor valve.	Total pounds of steam per hour.	Pounds of steam per brake horse-power per hour.

These tests do not show as high an efficiency as those made at Bordeaux, the difference being in part, no doubt, explained by the great difference between the sizes and rated powers of the two turbines. Mr. Goss appends to his Paper some account of tests made with a view to determine the starting effort of a de Laval turbine. To determine the maximum resistance under which the engine might be expected to start, the brake was clamped upon the flywheel so that the latter could not turn within it. Steam was then admitted to the engine, and readings were taken from the scale under the brake arm. The result of this process, of course, depends upon the steam pressure and the number of nozzles in action. With all nozzles, and with a steam pressure of about 125lb., the maximum starting power is equal to a force of 30lb. acting at a radius of one foot. The following tabulated data (Table IV.) gives the starting power for different pressures, and when two, three, or four nozzles are in action:—

ELECTRODYNAMIC ROTATIONS PRODUCED BY MEANS OF ALTERNATE CURRENTS.*

BY PROF. GALILEO FERRARIS.

Let O (Fig. 1) be a point in a space in which the magnetic fields produced by two electric currents are superposed. Let the directions O X and O Y of the two magnetic fields be different, say, perpendicular

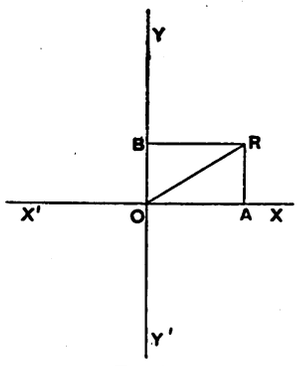

Fig. 1.

to each other. If the lengths O A and O B, cut off along the axes, give the intensities of the two fields, the diagonal O R of the parallelogram O A R B gives the intensity and direction of the resultant magnetic field. If the intensities of the magnetic fields vary with the time, the point R moves and describes a line the shape of which is determined by the law governing the variation of O A and O B; but at each instant the radius vector O R represents the intensity and direction of the resultant magnetic field at the point O. If the two currents are alternating and sinusoidal and of the same period, the intensities O A and O B of the two component fields are also alternating and sinusoidal; if they are represented by x and y respectively, they may be expressed in the terms of time t by the equations

$$x = A \sin \frac{2\pi}{T} t, \qquad y = B \sin \frac{2\pi}{T} (t + b),$$

where A and B indicate the maximum values, T the period, and $\frac{b}{T}$ the difference of phase between the two currents. Eliminating t between these two equations we obtain a relation between x and y which is the equation to the line described by the point R with respect to O X and O Y taken as co-ordinate axes.

When the difference of phase between the two currents is zero, or corresponds to one entire number of half-periods, the path described by R is a straight line passing through O, and on this line the point R traverses distances proportional to those traversed in the same time by A and B on O X and O Y. In this case the resultant magnetic field has a constant direction and an intensity varying according to the sinusoidal law, like the component magnetic fields. In every other case—*i.e.*, when the two currents are not reversed at the same instant—the path described by R is an ellipse, with its centre at O. In this case the vector O R, which represents the intensity and direction of the resultant magnetic field, is constantly different from zero, and rotates in the plane X O Y about the point O; in other words, we have a magnetic field which never becomes zero, and rotates about O. The rotating field goes once round during the time T, the period of each current. The direction of rotation is inverted if the phase of one of the currents is made different by half a period or an integral number of half-periods.

If, in particular, the directions O X and O Y of the component magnetic fields are perpendicular to each other, if the maximum intensities A and B are equal, and if the difference of phase is $\frac{1}{4}$, we have

$$x = A \sin \frac{2\pi}{T} t, \qquad y = A \cos \frac{2\pi}{T} t,$$

hence $$O R = A, \text{ and angle } A O R = \frac{2\pi}{T} t.$$

The path of R is therefore the circumference of a circle of radius A, and the point R traverses it with the constant angular velocity $\frac{2\pi}{T}$; in other words, we have then a magnetic field of constant intensity rotating about O with uniform velocity.

The effects above described may be produced by means of a single alternating current. It is, in fact, always possible in various ways to obtain the two currents necessary to produce the component magnetic forces from a single alternating current, and to vary the difference of phase between them within certain limits. One way of doing this is by letting the current pass through the primary coil of a transformer. Then the original current and the induced current are at our disposal. By letting those currents traverse two electro-magnets with their axes along O X and O Y, they may be used to produce the forces O A and O B. In order that they may present the required difference of phase it suffices to insert a suitable resistance in the secondary circuit; the difference of phase thus obtained tends towards a quarter-period as the resistance approaches infinity. But then the secondary current becomes too feeble, and must be corrected by altering the number of turns in the electro-magnets, so that A = B, and we have a constant field rotating with uniform velocity.

Another method of obtaining the same result consists in producing the two component fields from the two secondary currents produced in two transformers, or in two portions of the same transformer traversed by the primary current. Finally, to produce the forces O A and O B, two derived currents can be used. If in one of the circuits resistances free from self-induction are introduced, and in the other circuit a coil of small resistance and high self-induction, it may be brought about that while the mean intensities of the two currents are equal, or have a predetermined ratio, the phases of the currents themselves differ considerably.

Hence, by a simple alternating current operating in stationary magnets, it is possible to produce a rotating magnetic field, and all the effects obtainable from a rotating electro-magnet.

Among other things, the phenomena of induction produced by making an electro-magnet rotate near a conducting body may be reproduced by means of a simple alternating current, and thus the old experiments on magnetism of rotation may be repeated in a new form. If a conducting body is placed in the space where the two alternating fields are superimposed, the rotation of the resultant field produces in such a body induced currents, which, by Lenz's law, oppose the rotation of the magnetic field, and upon which the magnetic field reacts with forces which tend to whirl the body round in the same direction. If the conductor is movable, it rotates about O, just as if it were placed between the poles of magnets rotating about O.

I shall now describe some of the experiments by which I have verified and utilised this fact.*

Fig. 2 represents diagrammatically the arrangement adopted in a first experiment. The wires 1 A A A 1′ and 2 B B B 2′ represent two flat coils, the former consisting of a few turns of thick wire, and the latter of many turns of a thinner wire. The planes of the two coils are vertical and perpendicular to each other. They intersect along the vertical O O′, which represents the axis of the apparatus. The coil A A A of thick wire is introduced in the primary circuit of a Gaulard and Gibbs transformer. B B B is inserted in the secondary circuit, together with an adjustable resistance free from self-induction, by means of which the ratio between the intensities of primary and secondary current, and hence also the difference of phase between the two currents, may be varied.

* *Atti di Torino.* Vol. XXIII., pp. 360—375. Read March 18, 1888.

* These experiments were made in the autumn of 1885.

The transformer is arranged for a ratio of transformation equal to unity, but since a great difference of phase must be produced by inserting a high resistance in the secondary circuit, the reduction of the current must be compensated by increasing the number of turns. By suitably arranging the resistance inserted in the secondary circuit the two magnetic fields at the centre may be made sensibly equal while having a considerable difference of phase. This condition can be easily realised by trial. When it is obtained there is in the space between the two coils a magnetic field of approximately constant intensity, which rotates uniformly about the axis O O′, and makes a complete turn for each period of the alternating current. In this space is suspended a small hollow closed cylinder of copper C, by a wire O.

If the current is made to pass through only one of the coils, the cylinder remains stationary, but if the current passes through both coils in the manner indicated, the cylinder at once begins to move about its axis, twisting the fibre through many turns. If by means of a commutator the connections 2 and 2′ of B B B with the terminals of the transformer are reversed, thus producing a difference of phase of half a period in the current B, the rotation of the cylinder is reversed. If the reversal of the commutator takes place while the cylinder is moving in a certain direction, the speed decreases rapidly, the cylinder stops, and then commences to spin round in the opposite direction. The same effects are obtained if the two coils A and B are inserted in two derived circuits, one of which contains a resistance free from self-induction, while the other has only a slight resistance, but contains a coil with an iron core and considerable self-induction.

The experiments were repeated with the same results, substituting for the copper cylinder an equal cylinder of iron. If the cylinder

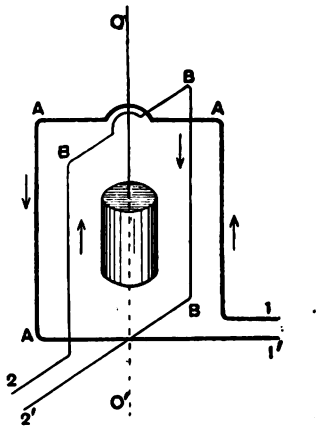

Fig. 2.

employed is small, and occupies only a small part of the space between the coils, the experiment succeeds as well with the iron as with the copper. When, on the other hand, cylinders are employed which fill up a great part of the space between the coils, the experiment succeeds less well with iron than with copper, on account of the high self-induction of the former. When, in fact, the coils A and B have a high self-induction, the necessary difference of phase cannot be obtained except by inserting very considerable external resistances, which waste a great part of the available energy.

In one experiment I employed a cylinder of iron, consisting of a number of discs separated and insulated by as many cardboard discs. In such a cylinder the induced currents by which the above result is explained cannot be produced, and yet the result is the same as before. In this case the rotation is due to the lag of the magnetisation of the iron discs behind the rotation of the magnetic field to which it is due.

The experiments above described, for the performance of which rough and improvised apparatus suffices, may serve not only as modifications of the classical experiments of Arago, Babbage, and Herschel for teaching purposes, but especially for showing the difference of phase between primary and secondary currents in a transformer, or the difference of phase between two derived alternate currents, or that between any two alternate currents of equal period. It is also easy to arrange the experiments in such a manner that they show the variation of the difference of phase as depending upon the variation of the resistances and self-inductions in the circuits.

If now we employ a light cylinder of copper, almost entirely filling up the space between the crossed coils, borne by a long bifilar suspension and provided with a mirror for reading with scale and telescope, we obtain a very sensitive instrument, which shows, even with currents of small intensity, very slight differences of phase.

3. Instead of suspending the movable conducting cylinder by a wire or a bifilar suspension, it may be mounted on a shaft running in bearings, and, by giving it larger dimensions, we obtain an electric motor for alternating currents. It is at once evident, and it also results from considerations which I shall go into later on, that a motor thus constructed would not be of any importance as a means of transforming electrical energy, but by its simplicity and by its properties it is open to some useful applications. I have constructed a provisional model of a motor, and have made some experiments with it.

Fig. 3 is a section of the motor made by a plane perpendicular to the axis of rotation. It may serve to give an idea of the arrangement of the principal parts of the machine. The movable portion of the apparatus consists of a copper cylinder, C, mounted on an iron shaft, O, and in contact with it. The copper cylinder is hollow and closed by plates of copper at the ends. Its outside diameter is 8·9cm., and its length 18cm.; it weighs 4·9 kilogrammes. The shaft O is 1cm. in diameter, and is mounted horizontally on two pivots. The fixed portion of the apparatus consists simply of two pairs of coils, shown in section in the figure at A A, A′ A′, and B B, B′ B′. One of these pairs of coils, A A, A′ A′, is arranged with its turns in vertical planes, and when it is traversed by a current it produces in the space containing the copper cylinder a field directed on the whole horizontally. The other pair, B B, B′ B′, has its turns in horizontal planes, and when traversed by a current it produces in the cylinder space a magnetic field whose mean direction is vertical. The coils are contained in wooden formers of rectangular form. Two of these, those for the coils B B′, only just allow the cylinder freedom to move. The other two, those containing the coils A A′, have the same breadth and a greater length, so that they embrace the two formers B B′ and just fit. When the four are in position they enclose a rectangular space *d e f g*, which is circumscribed about the cylinder C, leaving only space enough for freedom of motion. The gap between A and A′ and between B and B′ is only as wide as the shaft O. The coils A A′ consist of copper wires of 1·92mm. diameter, with 96 turns each. They are

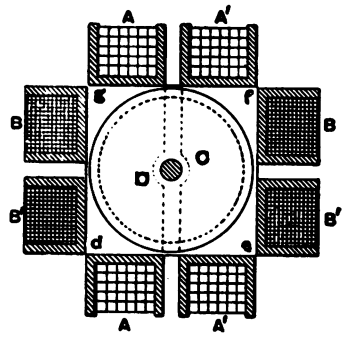

Fig. 3.

joined up in series so as to make a single coil of 192 turns. The total resistance of the two coils is 0·844 ohm. The coils B B′ consist of copper wire 0·97mm. in diameter, each containing 504 turns. The two coils are joined in parallel, so as to be equivalent to a single coil of 504 turns of double the section. The resistances of the single coils are 7·12 and 6·63 ohms: that of the two coils together is 3·43 ohms.

For driving the small motor I used a Gaulard and Gibbs secondary generator. The thick-wire coils were introduced in the primary, and the thin-wire coils into the secondary circuit. In the same circuit was placed a commercial rheostat free from self-induction, by which the intensity and the phase of the secondary current could be regulated. The resistance corresponding to the best running of the little motor was determined by trial. This resistance naturally depended upon the self-induction of the transformer, and upon the periodicity of the current employed. In my experiments the coils of the transformer were equal, and hence the self-induction of the secondary was equal to the mutual induction of both coils. The frequency of alternation was about 80 per second, and it follows from previous experiments upon the transformer that the apparent resistance due to the self-induction of the secondary coil was about 8 ohms. Under these conditions the experiment showed that the best running of the small motor took place when the resistance of the rheostat in the secondary circuit was 15 to 18 ohms. With the above numerical data it may be calculated that the resistance necessary to make the mean intensity of the magnetic field produced by the coils B B′ equal to that produced by the coils A A′ is comprised between those limits. It may also be shown that with the above resistances inserted in the secondary circuit, the difference of phase between the primary and secondary circuits must correspond to little under a fifth of a period.

Under these circumstances the copper cylinder of the motor commenced to put itself into motion when the current in the

Digitized by Google

primary circuit reached a value of about 5 amperes. With a greater current the cylinder acquired a velocity sometimes exceeding 900 revolutions per minute. Beyond this limit the imperfect centring of the cylinder on its shaft gave rise to vibration too violent to allow of the continuance of the experiment.

In the secondary circuit was inserted a commutator by which the connections of B B′ with the secondary transformer coil could be reversed. The rotation was then also reversed, or, if it was proceeding in one direction, it was gradually stopped and started in the opposite direction. A small dynamometer brake was attached to the shaft, in order to give some idea of the order of magnitude of the mechanical work and of its changes. The following table gives the number of revolutions per minute, and the corresponding power in watts :—

Revolutions per minute.	Watts.	Revolutions per minute.	Watts.
262	1·32	722	2·55
400	2·12	770	2·40
546	2·65	772	2·04
653	2·77	900	0·0

The mean value of the primary current was about 9 amperes, with 80 alternations per second. It will be seen that there is a maximum at about 650 revolutions per minute. On plotting the above figures as a curve, the first portion, up to 500 revolutions, is approximately a straight line. After that the curve bends down. This is due to imperfect centering. Otherwise the curve would reach a maximum at 1,200, and would then descend regularly until at 2,400—*i.e.*, the speed of rotation of the field itself—the available power would reach zero.

4. The relations between the couple producing the rotations, the useful work, the heat generated, and the velocities of the drum and the field, may better be investigated by assuming ideal conditions, *e.g.*, sinusoidal magnetic fields produced by equal currents with a difference of phase of a quarter-period. Under these circumstances the field is invariable and has a uniform angular velocity. Let this be Ω, and that of the drum ω, then their relative velocity will be $\Omega - \omega$. Putting M for the couple exerted by the rotating field upon the currents induced in the drum, W for the mechanical work given out in the unit of time (including that spent on passive resistances), we have

$$W = M\omega, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Putting P for the energy converted into heat in the unit of time by the production of the induced currents, we have

$$P = M(\Omega - \omega), \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

since the energy converted into heat owing to these currents is that spent in producing these same currents, and this is equal to the work necessary to maintain the relative velocity $\Omega - \omega$. Dividing (1) by (2) we have

$$\frac{W}{P} = \frac{\omega}{\Omega - \omega}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

or

$$\frac{W}{W+P} = \frac{\omega}{\Omega}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

i.e., the energy W, obtained as mechanical work or kinetic energy, is to the total energy W + P manifested partly as mechanical and partly as thermal energy, as the velocity of the drum to that of the field.

If, as supposed, the magnetic field is constant and rotates uniformly, there is a system of induced currents in the drum which always retains the same configuration. This system rotates about the axis, but the currents shift their places in the drum. The heat developed by the currents in the cylinder is therefore the same as if the currents were constant and stationary. But in each volume element the current is proportional to $\frac{\Omega - \omega}{\rho}$, where ρ is the specific resistance of the metal. Hence the heat is proportional to $\rho\left(\frac{\Omega - \omega}{\rho}\right)^2$, or to $\frac{(\Omega - \omega)^2}{\rho}$. If k is a constant, we can put

$$P = \frac{k}{\rho}(\Omega - \omega)^2,$$

Substituting this in (1) and (2) we get

$$W = \frac{k}{\rho}(\Omega - \omega)\,\omega \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1')$$

and

$$M = \frac{k}{\rho}(\Omega - \omega). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2')$$

Given the period of the alternate current employed, Ω has a definite and constant value. Hence (1′) shows that the energy W, manifested as mechanical work, is a maximum when

$$\omega = \frac{\Omega}{2},$$

whereas (2′) gives for M a maximum when

$$\omega = 0.$$

When the mechanical energy W is a maximum, or when $\omega = \frac{\Omega}{2}$, (3) gives

$$W = P,$$

so that then the mechanical work is equal to the heat developed.

5. These calculations and experimental results confirm the evident *à priori* conclusion that an apparatus founded upon this principle cannot be of any commercial importance as a motor, and while we may study its dimensions in order to increase notably its power and output, it would be useless here to enter upon any consideration of this problem. Still, the experiments described may be of some interest.

In the first place, the little apparatus may be useful for purposes of instruction. The couple is always in the same direction, and by the sole power of electro-dynamic forces, always feeble, great quantities of kinetic energy may be developed. In the second place, and this is more important, an apparatus like that just described may serve for measuring the electricity supplied by alternating currents. For this it would be sufficient to brake the movement of the drum by a resistance proportional to the square of the velocity. Since the moment of the moving couple is proportional to the square of the mean value of the current, the velocity of rotation would be proportional to the mean value. Thus the electricity supplied might be measured by registering the number of revolutions of the drum. The axis of the instrument should then be placed vertical, to diminish passive resistance and reduce faults of centring.

6. I have sought to repeat the experiments with an iron drum of nearly equal weight, but only a very slight rotation was obtained, owing to the high self-induction thus acquired by the coils B B′. An iron cylinder consisting of insulated discs as before also gave negative results. I also experimented with another kind of motor, where the drum rotated on a vertical axis and occupied the space between the cylindrically bored poles of four electromagnets facing each other in pairs. One pair was excited by the primary, the other by the secondary current. In this case iron gave better results than copper, but the effects were decidedly less than those before described, and for substantially the same reason as given above. Finally, I substituted a liquid conductor, say a mass of mercury, for the solid drum.

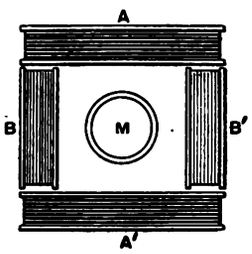

Fig. 4.

For this the following very simple arrangement was sufficient. The coils A A, A′ A′ and B B, B′ B′ were placed in vertical planes, two and two parallel and perpendicular to the other two, so as to form the four fours of a square prism. In Fig. 4 the four coils are seen in plan. They were joined to each other and to the generator as they were in the motor. A A′ were put in the primary, and B B′ in the secondary circuit, together with the rheostat and the commutator. A beaker M, full of mercury, was placed between the coils, and the rotations predicted were observed. Owing to the higher specific resistance of the mercury the speed acquired was much less than that of the copper. The maximum velocity with a current of 10 amperes was about 13 revolutions per minute.

THE COUNCILS OF TECHNICAL SOCIETIES.*

To criticise the council of a technical society is one of those daring acts that may be ranked with "speaking disrespectfully of the Equator." Fortunately, the Councils that deal with matters interesting to our readers afford very little occasion for criticism. They manage their affairs with conspicuous ability, and not only deserve, but also obtain, the confidence and gratitude of their members. Within the limits of their charter, articles of association, rules, bye-laws, or whatever the documents defining their duties may be called, they carry on the business of the society loyally and well, and display the same zeal in its affairs that they do in their own. Time and trouble are freely expended by men whose hours may be valued in guineas, and whose reputation gains nothing from the onerous position that they accept with so much goodwill. The average member has no clear idea what heavy demands are made

* From *Engineering*.

Digitized by Google

on his representatives, and how much actual work they do on his behalf. He sees the result, and appreciates it, but the efforts required to attain it are hidden from him. Nevertheless, he is so far aware of the great expenditure of thought and care that the affairs of a wide-reaching society require that he deems it his duty to show his appreciation of the council by not hampering their efforts by hasty criticism.

If the originators of technical societies were always gifted with prophetic powers, enabling them to foresee the lines on which science and society would develop, it is probable that the occasion would never arise when even the most radically-minded member could find matter for comment—other than laudatory—in the action of his council. But, as Sir Benjamin Baker pointed out in his recent Presidential address, engineers and scientific men go as wofully astray as statesmen in their prognostications of the future, and the arrangements they devise for the government of their societies become in time unfitted for the purpose. It is an evidence of Sir Benjamin's courage that he should have chosen such an opportunity to outline the scheme of a large reform in the Council of the Institution of Civil Engineers. A lesser man would have shrunk from the attempt, and rightly so—for reforms are dangerous matters except under the control of a strong will and powerful intellect. They either run into extremes and introduce more dangers than they remove, or else they result in mere tinkering, leaving the chief issue untouched and blocking the way for an unknown time against any true improvement. What it is that Sir Benjamin purposes will be found in his address published in our recent issues, and also in our article on page 607 *ante*? Briefly, he proposes to enlarge the Council and to add greatly to the scope of their possible duties. He would cease to elect it entirely from members living within easy reach of Westminster, and would include representatives engaged in practice in India, Australia, and Canada, as well as in the leading engineering centres of Great Britain and Ireland. The business of the Council would extend beyond the management of the affairs of the institution, and would include the interests of the profession. This enlargement of the Council would necessitate a change in the manner of voting. At present a member desiring to exercise his suffrage must be present at the annual meeting, an arrangement which practically disfranchises 90 per cent. of the members. This limitation of the voting powers of the members must surely have crept into the charter by inadvertence, since in other respects the document is drawn on a fairly broad and liberal basis, evincing full confidence in the wisdom of the members.

The machinery for election of President, Vice-President, and Members of the Council does not lend itself unduly to the retention of office by those that have once secured it. The appointment is for one year only, and can only be renewed by election. At the ordinary meeting next but one before the annual general meeting, which practically means a fortnight before, the Council present a list of persons whom they nominate as suitable for the offices of President, Vice-Presidents (four), and other Members of Council (15). To fill these 20 posts they must nominate not less than 29 corporate members, all the names, other than those of President and Vice-Presidents, being printed in the same character of type, and in alphabetical order. The members have thus 20 names to select out of 29, and it is their own fault if there is not a fair infusion of new blood each year. Further, they may erase any name or names from the list, and substitute one or more others.

Unless a member of Council of the Institution of Civil Engineers is popular, or is respected by the general body of the society attending the annual meeting, he is by no means certain of re-election, despite the fact of his nomination by the Council. But the same can scarcely be said of the President; with him nomination is practically election. According to the bye-laws the senior Vice-President must be nominated, unless he expressly declines the honour. It may be the opinion of a large proportion of the members voting that he is unfitted for the post, but unless they are equally united in the choice of some one else, he will win the election. The time between the appearance of the nomination paper and the taking of the vote is so short that for all practical purposes there is no opportunity for members to provide for concerted action. A great many may relieve their feelings by erasing the name of the President-elect, but unless they also all agree on whom they shall substitute, they waste their efforts. In our recent article on "The Head of the Profession," we spoke of the necessity of having an institution represented and guided by a man fitted to represent its members and its interests worthily and well, and of the dangers that surround a system of election by rotation. A Council is so bound together by friendships and associations that there arise occasions when it is almost impossible for them to choose the best man, unless they know it is not only theoretically but practically possible for the members to override their decision.

It will be interesting to compare with the constitution of the Institution of Civil Engineers the rules and methods of elections that prevail in some newer bodies, such as the Institution of Mechanical Engineers, the Iron and Steel Institute, and the Institution of Electrical Engineers. Taking these in the rotation named, we find that the Mechanical Engineers are ruled by a Council consisting of one President, six Vice-Presidents, 15 ordinary members of Council, and all the Past-Presidents. The President, two Vice-Presidents, and five members of Council (other than Past-Presidents) retire at each annual general meeting, and not the entire body, as with the Civil Engineers. The nomination of candidates to fill the vacancies takes place at the general meeting preceding the annual general meeting, the interval between nomination and election being three or four months, owing to the infrequency of the meetings. Prior to the meeting at which the nomination takes place, the Council issue to the members a nomination list, which includes the names of such retiring members of Council as offer themselves for re-election and also some additional names, the total number of names suggested being, as a rule, three or four in excess of the number of vacancies. Then at the meeting itself any member present may nominate one or more other persons for positions on the Council, and the names of the persons so nominated are added to those nominated by the Council, and are included in the ballot list, which is posted to members. It is thus possible for any member to propose any other, either as member of Council, Vice-President, or President; indeed, there is nothing in the rules to show that he may not propose himself. As a matter of fact, it is common and customary for one or more members to be proposed and seconded at the final meeting each year, and it is only by consulting previous lists that the majority of voters can discriminate between the nominees of the Council and of private members. The voting papers are transmitted by post, and hence all can join in the election, whether present at the meeting or not. Under these arrangements the powers of the members are real, and easily applied. It is worthy of notice, however, that in spite of the popular and democratic constitution of the Institution of Mechanical Engineers, it is in one respect more conservative than the older Institution. Past-Presidents form an integral and irremovable part of the Council, with voting powers the same as the elective members. There are at present 10 Past-Presidents, as against 21 elective members. There is thus, as it were, a House of Lords and a House of Commons sitting in one chamber and voting together.

When a suggestion is made that the constitution of an institution shall be altered in the direction of placing the nomination and election of Council more in the hands of the members, the conservative element generally prophesies that there will cease to be any continuity of policy owing to incessant changes in opinion that pass in waves over a democratic body. The history of the Iron and Steel Institute is a complete answer to this plea. It has a more liberal constitution than either of those we have noticed, yet its career has been singularly free from radical action on the part of the electorate. The retiring members of Council are elected again and again; there has only been one contested election for many years, showing that the members are perfectly satisfied to forego the exercise of their privileges. The Institute is managed by a President, nine Vice Presidents, and 15 Members of Council. Past-Presidents are *ex officio* permanent members of Council; at present there are seven of them. The President is elected for two years; three Vice-Presidents and five members of Council retire annually in rotation, but are eligible for re-election unless disqualified by non-attendance during the previous year. At the ordinary meeting preceding the annual meeting the Council presents a list specifying which of their number are eligible for re-election. Any member is then entitled to add names to the list of candidates, and names may be sent to the secretary for addition to the list up to one month previous to the annual meeting. The voting papers are sent and returned by post, and may, of course, contain more names than there are vacancies. There is a considerable interval between nomination and election, and ample time is available for members to confer together and propose additional names after the publication of the first list. Whether or not there is anything in the manufacture of iron and steel that conduces to a satisfied and pacific frame of mind, we cannot say, but the fact is that there is no society that enjoys a more peaceful career than the Iron and Steel Institute, nor is there one in which the Council is more unfettered in its action. Possibly this arises from the fact that the members never suffer from the irritation of feeling themselves impotent to influence the action of the Council. They have, further, the somewhat unusual power under Section IX. of the rules "to appoint such consulting officers as may be thought desirable from time to time."

The Institution of Electrical Engineers is the youngest of the four societies we are considering. It has passed through several transformations to accommodate itself to the altered conditions of the industry it represents, and hence has had ample opportunities of modifying its constitution if any change were needed. The Council comprises a President, four Vice-Presidents, 12 ordinary members, three associate members, and all the Past-Presidents. Of the latter there are 13, a remarkable illustration of the adage

Digitized by Google

"Electricity is life." The four Vice-Presidents retire annually, as well as the whole of the Council. At each retirement three members of Council and the three associate members are ineligible for election during the following year. The Council prepare, previous to the annual general meeting in each year, a list of members whom they propose as suitable for the offices of President and Vice-Presidents. The list also contains the names of a sufficient number of members and associates to fill the Council. A copy of the list is forwarded to the voters not less than seven days before the annual meeting, and each member is at liberty to make a selection from the list, and to substitute the name of any qualified person for each respective office. As a matter of fact the list contains the exact number of names to fill the vacant offices, and there is no provision for other names to be added to it at the instance of private members before it is finally issued. The constitution of the Institution is less liberal in every respect than either of the three we have already considered, with the single exception that the personal delivery of voting papers is not required. The time for deliberation is the shortest of the four—seven days, against 14 in the Civil Engineers. Even these seven days are not really available, for the natural impulse of the country member is to fill up his Paper and return it the day it is received. In any case, seven days are not sufficient for concerted action to be organised, and other names to be substituted by a majority of the members for those submitted to them. The Past-Presidents vote in the Council, as with the Mechanical Engineers and the Iron and Steel Institute; but, unlike the case of those bodies, the Past-Presidents make nearly half of the Council, and are thus almost on a par with the elected body. A large proportion of the Council is thus permanent, and consequently must grow out of touch with the members. The reason of this state of affairs is to be found in the practice of electing a new President each year. In the Iron and Steel Institute the election is for two years by the rules, and among the Mechanical Engineers the same practice obtains by custom. The Institution of Electrical Engineers commenced with a number of eminent and distinguished men on its roll, and hitherto it has had reason to be proud of the occupants of its chair. It also contains an unusually large number of young men who have yet their reputations to make, and who for many years will not be suitable to fill the highest office. In a short time the dilemma will have to be faced of either electing some of these, or of habitually re-electing those that have already pressed the chair. The Mechanical Engineers, with their much larger roll, containing a greater proportion of men of mature age, find that the claims of all that can justly aspire to the presidential office can be met on the basis of a two years' term, and it is well worth the consideration of the Electrical Engineers whether the same course would not be worth their following. From the accidents of the origin and development of the society there must necessarily be a great gap, not only in age, but also in ideas and in aspirations between the Council and the members, and it is conceivable that this might develop into a positive want of sympathy should the feeling arise that the Institution was being "run" from the Council table. As we have already remarked, the possession of a democratic constitution renders a society the more ready to give practical proof of its confidence in its Council by leaving its affairs in their hands.

We have been induced to give this recapitulation of the constitution of these societies by the fact that reform is in the air. Sir Benjamin Baker has started the subject, and under his initiative other technical bodies need not be ashamed to inquire if there is any imperfection in their arrangements. When science and practice are constantly developing, there is the danger of engineering societies getting out of harmony with their environment, unless from time to time they take stock of themselves and their surroundings.

THE THERMOPHONE.*

In the Newport, R.I., gas and ice factory use is made of an instrument called the "thermophone," for determining the temperature at different points in the gas-holder tanks. The apparatus was designed by Messrs. H. E. Warren and G. C. Whipple. It resembles the Siemens pyrometer, and takes advantage of the fact that different metals have different electrical temperature coefficients. The accompanying diagram illustrates the general arrangement.

A and B are coils of different metals placed in proximity and joined together as shown in the figure. These coils are connected with a slide wire, C D, by means of the leading wires L and L¹. The two ends of C D are connected in circuit with a battery, M. A galvanometer, G, is put into a leading wire connecting the junction of A and B with a movable contact, Y, on the slide wire. The galvanometer will indicate zero current when $\frac{A}{B} = \frac{CY}{DY}$. But A and B, having different temperature coefficients, will vary in resistance at different rates with changes in temperature; consequently there will be a different value of $\frac{A}{B}$ for every temperature. The value of $\frac{A}{B} = \frac{CY}{DY}$ may be directly read from a scale placed under the sliding contact Y, or the temperature corresponding to the given ratios of $\frac{A}{B}$ may be marked upon the scale.

In practice the slide wire is wound around the edge of a disc above which there is a dial graduated in degrees of temperature. The hand on the dial is directly over the movable contact on the slide wire, and both are moved by turning a knob in the centre of the dial.

It is easily seen that the temperature of the slide wire C D has absolutely no effect upon the reading of the instrument, for being made of one piece of metal, which has the same temperature throughout its length, each portion of it will rise or fall in resistance at the same rate with changes in temperature; consequently the ratio of its parts will not vary. The effect of temperature changes on the leading wires L and L¹ will not sensibly affect the readings for the same reason.

In place of the galvanometer it has often been found advisable to use a telephone, in connection with a circuit-breaker, to show the presence of a current. It is in this form that the instrument is illustrated here. The coil having been placed in the position where the temperature is desired, the transmitter is taken from its hook on the left-hand side of the box and held to the ear while the right hand of the operator turns the knob over the dial until a point is reached where no sound is heard. The dial hand then indicates the true temperature. If desired, a number of coils can be located permanently at a number of distant points, and thrown into connection with a central dial box, at will, by means of a little switchboard.

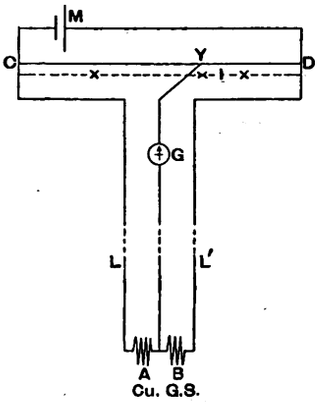

Diagram of Connections of the Thermophone.

MUNICIPAL TELEPHONY.

The following is an abstract of the discussion on Mr. A. R. Bennett's Paper on "Municipal Telephony," which was read before the Northern Society of Electrical Engineers on November 11th, and appeared in *The Electrician* of November 15th:—

In a written communication Mr. Henry Edmunds said that he would point out that competition in such a matter as telephony must inevitably result in absorption, or in public inconvenience. When, in one district, there were rival telephone systems, the subscriber had to pay for both. A case in point occurred in Manchester itself, where 500 of the subscribers to the Mutual Company had to become subscribers to the National also. Consequently, instead of paying merely £4 or £6 for their telephone service, as Mr. Bennett made out, these 500 were compelled to contribute some £15 or £16 per annum. It was hardly fair to compare an isolated little Norwegian town of 30,000 inhabitants, with the English industrial centres. If each small town had its own system, with varying rates, varying conditions, and varying management, the confusion could be better imagined than described. The same thing applied to every great town in the kingdom. Liverpool, for example, had within its telephone area three county boroughs, and 12 local boards. London had within its telephone area the whole County of London (which alone possessed a population of 4,230,000 as against the 30,000 of Trondhjem) and also the towns of Dartford, Reigate, Redhill, Croydon, Epsom, Richmond, Kingston, Tilbury, Woodford, Romford, Epping, West Ham, Harrow, Ealing, and Hampton Court, all included in one rate. Even according to Mr. Bennett, at Trondhjem there was no royalty to pay, no way-leaves, no night service, no telegram service. With nearly 800 subscribers there were no multiple switchboards. Furthermore, the Norwegian system was not being worked under the conditions of a limited tenure. It was shown before the late Select Com-

* Abstract from the *Electrical Engineer* of New York

Digitized by Google

mittee that if the National Telephone Company were relieved from these direct and extraneous charges (which did not press, or very lightly pressed, upon the telephone systems abroad) that the average annual subscription in this country would be reduced to £6. 5s. 11d., including London, where the rates were higher than in the provinces. It was also shown that the present working expenses of the National Telephone Company (including the items above referred to) amounted to £6. 4s. 7d. per line, without taking into account interest upon capital or depreciation of capital. It must, therefore, be assumed that the Mutual Telephone Company, with its subscription of £5 or £6, would have quickly reached the bankruptcy court, when the condition of affairs had become normal, and its working expenses had reached those of the National Company.

Mr. BENNETT stated that the subscription of the Dundee Company was £5. 10s. per annum, and that it paid an average dividend of 9 per cent. during the 4¼ years of its existence. It may be pointed out, however, that in the earlier part of the Company's existence its subscription was £10, and the Chairman of the Dundee Company said before the late Select Committee, "I think we allowed too little for depreciation, and I think if we had gone on we would not have been able at the £5. 10s. rate to have paid anything at all. After the rate was reduced to £5. 10s. the dividend was reduced to 5 per cent."

Mr. THOMSON said he had taken much interest in the telephones of Manchester, he having been one of those who tried to oppose, by the establishment of the Mutual Company, the great hold which the National Telephone Company had upon the country. It seemed to him clear from the amount of "water" and other useless capital which the National Company had, that whatever that Company could do, the people of Manchester could erect wires and appliances over the town very much cheaper themselves. He thought that the amount of £6. 4s. 7d. for working expenses per line which was given by the National Telephone Company was out of the question as compared with the small figures which Mr. Bennett had shown with companies who possessed no useless capital. Of course, as the telephones increased in number the demand for telephones would be greater and the number of times per day which each wire would be used and the consequent cost per wire would be greater on a large than on a small exchange; but the record given by Mr. Bennett of what could be done at Stockholm for £4. 8s. on a 14,000-wire exchange showed that the charges for the wretchedly small exchange in Manchester and Salford were absurdly too high. For himself, he used the telephone perhaps three or four times per week, and he was quite satisfied to pay £5 or £6 per year for that favour. At the same time he did not use the telephone sufficiently to make it worth £10 per year to him, as that would cost an average of about 1s. per message. He thought that it was strange that the municipality of Manchester had not taken more interest in this matter, the reason no doubt being that it was very difficult to make gentlemen who had many other matters on their minds to clearly understand the telephone question. He himself four years ago had tried to show the telephone users in Manchester that if they paid £20 for one telephone they could have two for £15 by joining the opposition, but many seemed to think that they would get the benefit of the opposition without joining it themselves, and so the work required by those actively engaged in the opposition was increased many fold by the general public inertia, and thus practically it had come that Manchester people were for the moment bound hand and foot and laid at the mercy of the very worst form of monopoly. He trusted that the Manchester Corporation and the other corporations throughout the country should have telephonic exchanges of their own, which would certainly produce ample interest on the capital expended, and profit if the people were allowed to pay a reasonable amount for telephonic communication. He thought that a telephone should be constructed in Manchester at rentals sufficiently low to allow of the formation of a very large exchange in place of the wretchedly small one which existed under the present monopoly, and as the trunk lines would next year be in the hands of the Post Office it could be very easily arranged that they should send messages from one town to another through the Post Office wires. He hoped that that Society would use its influence to lay some stress upon the Manchester Corporation with a view of getting it to establish a municipal telephonic service.

Mr. MARR said it was all very well to talk of watered capital—and they all knew pretty well what it meant. On the other hand, on starting a new industry, such as the telephone business was, it became impossible to do away with watered capital, owing, in a large sense, to the element of doubt as to whether it would be successful or not; and if his information was correct, Prof. Bell himself received something like three-quarters of a million in cash and shares, directly and indirectly. Those shares required a dividend, and must go down as watered capital. It seemed to him that the position of to-day with regard to telephone rentals in Manchester, and increased rentals all over the country, was caused by the Government not taking it up in the first instance, and, having regard to the fact that the law courts gave the decision that a telephone was a telegraph, and came under the Telegraphs Act, it seemed to him that the only solution of the question lay in the Post Office taking it over and working it.

Mr. CALVERT said he was intimately acquainted with the Scandinavian system, and he would just like to make a few remarks on the matter. He thought it was rather a pity that Mr. Edmunds was not there to reply, but, at the same time, of course, he would not criticise in any way unjustly. He understood that Mr. Edmunds said if every corporation had its own telephonic system, with State trunk lines between the different corporations, that that would lead to a great deal of confusion. Now that was just what Sweden had. He thought it was rather a pity that Mr. Bennett had taken such a small town as Trondhjem. For example, particulars as to Stockholm would have been better. Stockholm was a town of 260,000 inhabitants, and had probably more telephones than any city in the world on its population basis. There were 14,000 telephones, one for every 18 men, women, and children in the place. When the State took over the Stockholm Bell Company the Stockholm General Company would not sell, and the State could not compel them. The General Telephone Company would not sell to the State, but it had just been arranged in a friendly way, and there was now inter-communication between the concerns, so that anyone on the General Telephone Company could telephone on to the State lines. Coming back to the point of inter-urban communication, the State in Sweden owned, of course, all the trunk lines up and down the country. They then made arrangements with the urban companies to allow inter-communication on payment of a certain fee, simply for the trunk line, and there was no confusion whatsoever. The state of telephony in Sweden was probably most complete as regards the rapidity of communication. In a town like Stockholm, with one central station, 8,000 wires went up to one tower, and he could stand in his office and get 10 communications in 10 minutes, so rapid was it. He said that as soon as he rang the answer came instantly, and the communication was made. This was not the case in England. As regarded the cost—well, it was of course exactly as Mr. Bennett had put it. The general price in Sweden was about 80kr.—that is to say, £4·80, but the small towns and villages had it for about 27s. 6d. per annum, and then inter-communication, for which they paid each time. Most business men had the metallic circuit, the extra wire being laid for a small extra cost once and for all. This was one point which Mr. Bennett had not dealt with. They had to take into consideration that, in the first place, there were no wayleaves required to be able to put up telephones. In the second place, there were relatively bad postal arrangements, which make it absolutely necessary for men to have telephones. The result was that there was scarcely a farmer in all the country with a few acres of ground who had not a telephone. Then, of course, the wages were fairly low in some respects, although the girls got practically as much as in England. There was also one little point about the price of the poles. He thought the price given by Mr. Bennett could not be correct.

Mr. BENNETT, in reply, said that he was sorry Mr. Edmunds was not there, because it was necessary to take very strong exception to some of his remarks. Mr. Edmunds seemed to have favoured the Society with an extract of the evidence given before the late Select Committee by the National Telephone Company on its own behalf, but omitting the cross-examination, which showed that many of the statements made were not susceptible of substantiation. Taking the statement that 500 of the subscribers to the Mutual Company had to become subscribers to the National Company also. Actually the exact converse was the case. These 500 subscribers were already members of the National Company's Exchange, and in order to obtain a prompt and efficient local service they joined the Mutual Company also. Mr. Edmunds said that it was not fair to compare a Norwegian town of 30,000 inhabitants with the English industrial centres. He (Mr. Bennett) had done nothing of the kind. What he asserted was that the example of Trondhjem was applicable, with very slight modification, to British towns of the same size; for a comparison with our larger cities he went to Stockholm and Christiania. Mr. Edmunds had enumerated the various divisions of Manchester and Salford, and assumed that it would be necessary, under municipal management, to have a separate licence, a separate exchange, and a separate set of tariffs and regulations for each district. That sort of thing was made much of before the late Select Committee, but the witnesses from Edinburgh and Glasgow repudiated the notion, pointing out that Edinburgh, for instance, serves Leith, Portobello and other outlying boroughs with water, with gas, and also in some cases with tramways, and the same state of things obtained in other Scottish as well as English boroughs. It would be the same with a municipal telephone exchange. Mr. Edmunds also enumerated the names of various districts and towns around London and said that all of them were included in one rate. Was Mr. Edmunds aware of the fact that in most of the places he named there were no telephone exchanges at all, and that in some of them there was not even a solitary telephone wire, although, in the majority of cases, the respective populations far exceed that of Trondhjem? Mr. Edmunds said further that the Norwegian system was not being worked under the condition of a limited tenure. In this he was not quite correct; but if he were, what had limited tenure to do with the people who wanted cheap and good telephones? Mr. Edmunds was evidently a thorough advocate of the National Telephone Company. He (Mr. Bennett) was not an advocate against it. His advocacy simply extended to the right of the public to have an economical and efficient telephone service and the right of the telephone industry to be free in this country—matters which had nothing to do with considerations of limited tenure or with the interests of existing telephone companies. Mr. Edmunds further said that it was shown before the late Select Committee—"alleged" would have been a better word—that if the National Company were relieved from extraneous charges that the average annual subscription would be reduced to £6. 5s. 11d. It was also shown, he said, that the present working expenses of the National Company amounted to £6. 4s. 7d. per line. He (Mr. Bennett) would like the Society to compare this statement with that made on the same point by the National Telephone Company to the Manchester Town Council when negotiating the agreement which had been mentioned during the discussion. According to Alderman Milling, as reported in the *Manchester Guardian*, the National Telephone Company stated that out of £10 received from subscriptions £8 went in expenses, £1 to Government, and there remained only £1 for dividend and renewals. This makes the working expenses per line more than £9, while the Select Committee was told that the amount was £6. 4s. 7d. per line. Which of these two statements was correct? Both cannot be, yet the authority was the same. The fear expressed by Mr. Edmunds that the Mutual Company would have quickly reached the Bankruptcy Court was superfluous, as they never could, by any possibility, have done so. Mr. Edmunds stated that the whole of the outside plant of the late Dundee Company of the late Mutual Telephone Company had had to be taken down and renewed. Mr. Edmunds was wrong here. As regards the Mutual Company's plant it was still up and still working, as there were over 1,000 subscribers still connected to the exchange. As regards the

Digitized by Google

Dundee and District Company's plant, it was true that much of it was taken down, but not because it was badly constructed and of no use. The reason was quite a different one. He was personally acquainted with the facts of that case, and he could say that Mr. Edmunds was quite mistaken. Mr. Edmunds said that the rate of the Dundee Company was originally £10, and that after it was reduced to £5. 10s., the dividend fell from 9 per cent. to 5 per cent. ; but the £10 rate of the Dundee Company endured but a very short time, and the development which took place under it was exceedingly small. Practically the whole of the Company's good work was done on a £5. 10s. rate. That Company had to contend against exceptional obstacles, as the patents were in full force during its existence, and its greatest difficulty was in obtaining instruments that it could use without fear of infringement. But nevertheless that Company paid a dividend of 9 per cent. per annum for the 4¼ years of its existence, and ultimately got its capital back with 40 per cent. added. It also compelled the National Company to undertake never to raise the rate in Dundee beyond a figure which was exactly half of that on which the National subscription stood when the competition commenced. So much for the results of competition. Mr. Marr mentioned the Post Office telephone service, and inquired why only 1,300 subscribers to it could be found in all the United Kingdom. There was very small inducement in the matter of rates for the oppressed to fly to such a sanctuary as was afforded by Her Majesty's Post Office. Secondly, the spirit of Post Office management was inimical to the development of such a business as the telephonic. The Post Office officials sat in their offices and waited for business to walk in to them. Mr. Marr remarked that companies could seldom do without "water," and that large sums were paid to the inventors of the telephone. If Mr. Marr would look into the matter closely, he would find that the money paid for the patents was not included in the "water" part of the capital. Before the late Select Committee, the National Telephone Company admitted the existence of £1,292,000 of "water," but this was entirely made up by amalgamations with, and acquisitions of, other companies. Mr. Marr also asked for information as to the present state of the agreement between the National Telephone Company and the Manchester Corporation. In his (Mr. Bennett's) opinion the present state of affairs was that the Manchester Corporation had put itself absolutely and entirely under the heel of the Company. Alderman Leech warned them of what they were doing at the time, but ineffectually, and the consequence was that unless the citizens of Manchester made a prompt remonstrance they would soon find the Company had acquired what would shortly become an unchallengeable monopoly. Before the late Select Committee the Institution of Electrical Engineers, through the medium of their President (Mr. Crompton) and of Prof. Silvanus Thompson, gave evidence as to the evil wrought to the electrical industry by the present monopoly, and expressed opinions strongly in favour of competition. His suggestion was that the Northern Society of Electrical Engineers should render help in the same direction. If the Northern Society would appoint a committee to watch the progress of the telephone question, and take such action thereon as might appear desirable in the interests of the electrical industry generally, he was sure that the Society would be performing a good work both for itself and the public. In conclusion, he would like to explain that he had instanced Trondhjem, because that town was at present the best example of a telephone exchange managed by a municipality. Before the late Select Committee it was said in effect that municipal authorities were not capable of managing a business such as a telephonic exchange, and they had heard that opinion re-echoed to-night in Mr. Edmund's remarks. He thought that such an allegation ought to be proved or disproved, and the Paper he had given them this evening was, he thought, a very complete refutation of it. After Trondhjem there remained the greater example of Christiania, and soon the exceedingly important towns of Rotterdam and Amsterdam would be added to the list.

LONDON CHAMBER OF ARBITRATION.

Up to the present the electrical industries have been comparatively free from trade disputes, and we sincerely trust that such a satisfactory state of affairs may long continue. If Boards of Arbitration, or Councils of Perfection, or under whatever other name such bodies may prefer to be designated, have any *raison d'etre*, it may reasonably be presumed that the most opportune moment for its conciliatory functions to be exercised is on the first serious conflict between employer and employed in a new industry, and it is, therefore, to be hoped that, should such a deplorable event occur in connection with the Electrical Trades, the London Chamber of Abitration will make special efforts to ensure its voice being heard for peace. A report, dated November 15, 1895, has just been printed and circulated amongst members of the Court of Common Council of the City of London, which is signed by Messrs. H. Clarke, A. Rollit, A. Pursell, J. Chambers, W. J. Thompson, jun., and F. G. Burmester, as to the working of the Chamber since its establishment on November 23, 1892. The report states that :—

The Chamber was established with the object of providing for the speedy and inexpensive settlement of commercial disputes, and although the number of cases which have been brought to the Chamber has been less than was anticipated by its founders, the Corporation and the London Chamber of Commerce, it has achieved in a large measure the object for which it was instituted. The average time occupied in the disposal of the cases which have been heard in the Chamber, from the lodging of the submission to the award, has been ten days, whilst one case was recently completed in so short a period as six days. The amount of the fees in each case has not exceeded, in the average, five guineas, and this notwithstanding that several important disputes, involving in some instances large sums, have been dealt with. Those who have had recourse to the Chamber have been exceedingly satisfied with its working, and have expressed their surprise at the rapidity with which cases have been carried through and the smallness of the expenses incurred.

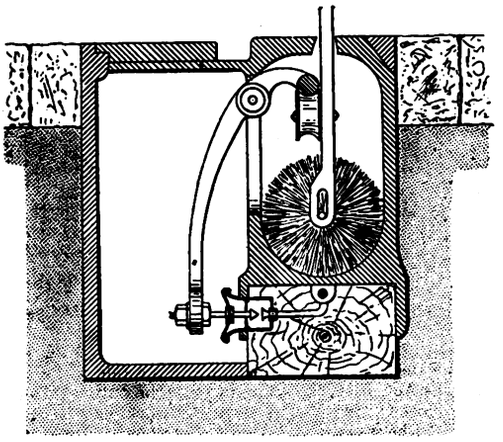
The establishment of the Chamber awakened considerable interest on the part of the public and the Press, and suggestions were freely made that the Law Courts might with advantage bring their method of procedure more into harmony with the wants of commercial men, especially in reference to rapidity and the avoidance of long vacations. These suggestions have already borne fruit, and the establishment of a Commercial Court is now an accomplished fact.

The members express themselves confident that with time Chambers of Arbitration in this country will attract as much business as some of the largest tribunals of commerce on the continent. In proof of which it is stated that Chambers of Arbitration have been recently formed in the provinces, and even in the Colonies, with rules similar in provision to those of the London Chamber of Arbitration, and in some cases identical. As evidence of the success of the arbitration idea amongst commercial men it is mentioned that some of the arbitrators engaged by the Chamber have been engaged in outside arbitrations.

Several modifications in the existing rules are recommended. In reference to the complaint that the existence of the Chamber is comparatively unknown, it is pointed out that the proceedings of the Chamber are necessarily conducted in private, as commercial firms object to the decisions come to in the cases submitted to arbitration being made public. It is, however, intended to issue a printed letter, giving full information as to the advantages of the Chamber, and particularly drawing attention to the fact that the Chamber is under the management of the London Corporation and the London Chamber of Commerce, to every Chamber of Commerce both in the United Kingdom and abroad, with a request that they will advise their members to insert in their London contracts the arbitration clause referring any dispute that may arise to the London Chamber of Arbitration ; and, further, it is intended that the Chamber shall from time to time be suitably advertised.

BURT CONDUIT SYSTEM OF ELECTRIC TRACTION.

Our American contemporaries have recently contained accounts of a somewhat hopeful-looking system of electric traction on the underground conduit system. This system, which is due to Mr. John Burt, is on the sectional conductor plan, and does not in any way rely upon electromagnetism for effecting the necessary contacts. The sectional conductors are supported, as shown in the illustration, on the upper ends of bell-crank levers, the lower ends of which make contact through stuffing boxes with the insulated feeder which runs along at the bottom of the conduit. The car makes contact with the sectional conductor by means of a pair of under-running trolley wheels secured to a stout iron frame. When the trolley wheel comes into contact with the extremity of one of the lengths of conductor, it lifts that end, and causes the lower



end of the lever to make contact with the insulated feeder. When it has got beyond the centre of the section, the upward pull of the under-running wheels causes the back end of the sectional conductor to fall, and to break contact with the insulated feeder, the forward end of the conductor being now lifted, causing the lower end of the lever at that extremity to make contact with the insulated feeder. The successive lengths of conductor are joined by flexible insulated joints. The distance between the two wheels of the contact maker is sufficient to bridge over these breaks. As will be seen in the illustration, the lower end of the frame which carries the trolley wheels also carries a brush. The spindle of this brush is at an angle with the axis of the conduit, and the result is that as the car runs along, the brush sweeps out the conduit.

THE BIRTH OF THE POLYPHASE SYSTEM.

Among the observed phenomena of mental activity, there are perhaps none more striking, none more likely to reward a patient investigation, than the steps in the evolution of an invention. The history of engineering and electrical science at every stage bears witness to the fact that on mind, as on matter, "like causes produce like effects." It has been argued by one who bears an honoured name in the domain of electrical science, that the action of the mind is so regulated as to be capable of predetermination, so that, for example, it is possible to reconstruct the form of Shakespeare's plays, given the history of his life. Be this as it may, it is certain that historically hardly any invention or discovery can be said to have been originated solely by one mind, but frequently, within a few days of one another, by thinkers or investigators in many different parts of the world. It is this fact, realised by those to whom invention is a business or profession, which explains that somewhat undignified race to the patent office, and that hurried publication of half-matured researches so often commented upon.

These thoughts are suggested by a translation, which we publish in our columns to-day, of a Paper read by Prof. GALILEO FERRARIS before the Turin Academy in 1888. No full translation has, so far as we know, hitherto been published in English, but the importance to many of our readers of the subject of this Paper on "Electro-dynamic Rotations produced by means of Alternating Currents" has led to its appearance at what may seem a somewhat late period. We have already in these columns referred to claims which are being put forward in the law courts of the United States, France and Germany to the priority of NIKOLA TESLA as the inventor of the polyphase induction motor, and its use in the transmission of power, and as the Paper we publish to-day is relied upon in England and the Continent as a prior publication of the principles of such motors, it is likely to assume a position of importance. This Paper was published by being read to the Turin Academy on March 18, 1888, and the first publication

Digitized by Google

in England of TESLA'S invention dates with the date of his complete specification, May 8, 1888, nearly two months later. In America, however, this order is reversed, as TESLA'S various patents date in 1887 and early in 1888. To return, however, to the Paper itself, the first few paragraphs give in an admirably condensed form the geometrical conception of a rotating magnetic field produced by two sinusoid alternating currents differing in phase, but of the same period; then follows a description of how two currents differing in phase *may* be derived from a single alternating E.M.F., whilst Part I. closes by describing the mechanical effects producible by such a rotating field. Part II. describes actual experiments with several forms of apparatus made three years earlier, in 1885, to demonstrate the theoretical conclusions arrived at, and we have a motor described having a short-circuited armature nearly 9cm. in diameter and 18cm. long, which developed a maximum available power of 2·7 watts, whilst for comparison we may note that a machine of modern construction of the same size would probably develop 500 watts. It was, no doubt, because of this very small output that, after having shown the laws which govern the output and efficiency of such a motor, Prof. FERRARIS seeks to find the conditions of *maximum output*, and finds that this is reached (neglecting as he does leakage) when the speed of rotation of the armature is half that of the revolving field. But under these conditions he shows that the efficiency cannot exceed 50 per cent., and passes to the following conclusion:—"These calculations and experimental results confirm the evident *à priori* conclusion, that an apparatus founded on this principle cannot be of any commercial importance as a motor, and while we may study its dimensions in order to increase notably its power and output, it would be useless here to enter upon any consideration of this problem."

To anyone reading the Paper to-day with present knowledge the wonder must be that, with so clear an insight as Prof. FERRARIS evidently had of the principles of his invention, the forms which he designed were such as to give these small results. But in 1885 the magnetic circuit was hardly understood, and the motor was probably quite as far advanced as the transformer from which it was worked. It is not very clear in the Paper whether the actual phase difference (given as ¼th of a period) between the currents in the two coils was measured or calculated; if the latter it is at least reasonable to suppose that the phase difference may not have been as great as estimated, which might in part account for the small output. Just as the "evident *à priori*" statement, known as the law of Jacobi would have strangled the continuous-current electric motor in its infancy, if left to mathematics alone, so was this new departure left to die unrecognised by its parent. "Up to the summer of 1879 there seemed to be a curious misconception arising in the minds of even distinguished electricians, regarding the theoretical consideration of the efficiency of electric transmission of power. There are two distinct questions to consider. Do you want a motor to give out work rapidly? or Do you want the arrangement to transmit power most economically? The two questions are quite easy to solve and lead to quite distinct answers." We quote Prof. AYRTON, speaking in 1881 (*Proceedings* of the Society of Telegraph-Engineers and of Electricians, 1881, p. 118). Prof. FERRARIS wanted the motor to give out work rapidly, and seems to have omitted to notice the other and quite distinct answer. But because he did this the fact is not altered that in this Paper the essential principles at least of a two-phase induction motor, and the general theory of its action, are most explicitly given—so explicitly, indeed, that it would seem impossible for any serious claim to be made that this Paper was not a complete publication in this country of the polyphase induction motor. Particular constructions, particular methods of working—these may form the subject of subsequent invention, a very different matter to a broad claim such as has been suggested.

In thus reviewing this subject nothing is further from our minds than to belittle the work done by TESLA in the solution of this problem of polyphase motors, but there is no disguising the fact that those who controlled his inventions, partly from commercial, partly, perhaps, from personal motives, did not do much to develop them, and that they now seek to reap a harvest which is the result of toil and skill not their own.

ON POLARISATION OF ELECTRIC RAYS BY DOUBLE REFRACTING CRYSTALS.*

BY PROF. J. C. BOSE, B.A., B.SC.

A ray of ordinary light incident on a crystal of Iceland spar is generally bifurcated after transmission, and the two emergent rays are found polarised in planes at right angles to each other. The object of the present inquiry is to find natural substances which would polarise the transmitted electrical ray. It was thought that the analogy between electric radiation and light would be rendered more complete if the classes of substance which polarise light were also found to polarise the electric ray. The identity of the two phenomena may be regarded as established if the same specimen is found to polarise both the luminous and electric rays. As the wave length of an electrical ray is very large compared with that of visible light, one would think very large crystals, much larger than what occur in nature, would be required to show polarisation of electric rays. By working with electric radiations having very short wave lengths, I have succeeded in obtaining very satisfactory results with crystals of moderate size. These experiments show that certain crystals are double refracting as regards electric rays, and that they polarise the transmitted beam. With the help of a rudely constructed apparatus, I was able last year to detect traces of these effects. The apparatus has since been improved in detail; it is now possible to detect the polarisation effects with certainty. The usual optical method of detecting the bi-refringent action of crystals, is to interpose the double refracting structure between two crossed Nicols. The interposition of the crystal generally brightens the dark field. This is known as the depolarising effect, and is regarded as a delicate test for double refracting substances. There is, however, no depolarising effect when the principal plane of the crystal coincides with the polarisation planes of either the polariser or analyser. The field also remains dark when the optical axis of the crystal is parallel to the incident ray. A similar method was adopted for experimenting with polarised electric radiation. The electric ray is first polarised by a wire grating. A similar grating acts as an analyser. The two gratings are crossed, and the crystal to be examined is interposed. The receiver is a modified form of "coherer" with its associated voltaic cell and galvanometer. Brightening of the field is indicated by a throw of the galvanometer needle.

APPARATUS USED.

Radiator.—A small Ruhmkorff's coil is used for the production of oscillatory discharges between the two small metallic spheres, the diameterof each sphere being 1·5 c.m. The choice of a coil to produce electric oscillation has been a matter of necessity. I obtained oscillatory effects with ease and certainty by using a small influence machine of the replenisher type. But in the damp atmosphere of Calcutta, the satisfactory working of such a machine is a matter of great difficulty, at least for the greater portion of the year. I had therefore to abandon the influence machine with regret, and to use a Ruhmkorff's coil instead. This coil caused me the greatest trouble. The discharge would of a sudden cease to be oscillatory; after a great deal of coaxing it would work satisfactorily just for a short time. The only coil I could get was a badly constructed one, with defective insulation. I made it serviceable by changing the condenser and improving the vibrator. By looking to many points of detail, I succeeded in making the apparatus work with fair uniformity for several hours. It must be borne in mind that the receiving apparatus also requires careful adjustment.

Among the possible causes of unsteadiness may be mentioned the following:—(1st) The current actuating the coil may vary after a time. To overcome the difficulty a fairly constant battery was made to charge a small storage cell, and a derived circuit from this

* From the *Journal* of the Asiatic Society of Bengal.

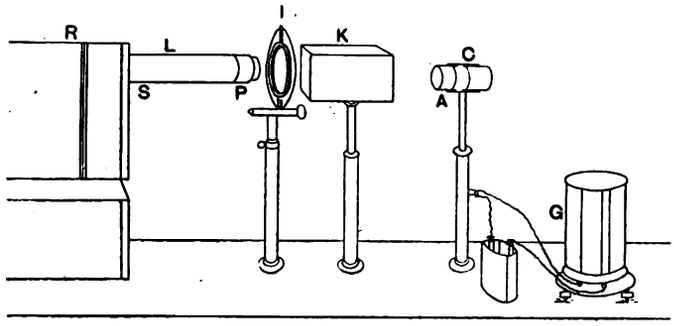
Digitized by Google

cell was led to the primary coil. (2nd) The interrupter may have its rate of vibration changed by heating, wearing out of contact points, and other causes. Any change in the periodicity of the vibrator is at once made evident by the corresponding change in the pitch of the note given out by the vibrator. (3rd) The sparking balls may have their surfaces roughened by the disintegrating action of the spark. To avoid this difficulty the balls were thickly coated with a deposit of gold, and were turned round at intervals to expose fresh surfaces.

The coil with a storage cell is enclosed, with the exception of a horizontal tubular opening, inside a metallic box (*see* figure), not dissimilar in appearance to an optical lantern. The interrupter is actuated by turning a key from outside. The sparking balls are at one end of a brass tube 25 c.m. long and 5 c.m. in diameter. At the further end of the tube is the polariser. Inside the tube is placed a convex lens with the spark gap at its principal focus. With the help of the lens and suitable diaphragms, the electrical beam is made approximately parallel. By means of an iris diaphraghm the amount of radiation may be varied.

Polariser.—The success of the experiment depends greatly on the care with which the polariser and analyser are constructed. Fine copper wire 2mm. in diameter is carefully wound in parallel lines, round two thin sheets of mica. There are about 25 lines for every centimetre. The mica pieces are then immersed in melted paraffin, and the wires thus fixed *in situ*. By cutting round, two circular pieces, containing the gratings are obtained. The mica pieces are too thin to produce any disturbing effect. The gratings are fixed with wires parallel, at the ends of a tube 5cm. long. This polariser tube rotates inside the outer end of the tube which sends out the parallel electric beam.

Analyser.—The analyser is similar in construction to the polariser. It rotates inside the receiving tube, which contains the sensitive surface for detecting radiation.



Polarisation of the Electric Ray.

R=Metallic box containing Rhumkorff coil. S=Position of sparking balls. L=Position of convex lens. P=Polariser. I=Iris diaphragm. K=The crystal. A=Analyser. C=Coherer. G=Galvanometer (placed at a distance).

Receiver.—The receiving apparatus consists of a "coherer" with a voltaic cell and galvanometer in series. The coherer is modified from its usual tubular form. The filings, a single layer thick, are spread over a large surface. This arrangement secures great sensitiveness. A pair of insulated wires from the ends of the coherer, are led out to a distant dead-beat galvanometer of D'Arsonval type in series with a constant cell. The leading wires are shielded from radiation by enclosing them inside two coatings of tinfoil along the whole length. As an additional precaution the galvanometer is also enclosed in a metallic case, with a slit in front of the galvanometer mirror. A spot of light reflected from the mirror is received on a scale. By adjusting the electromotive force of the circuit the sensitiveness may be increased to any extent desirable.

When the analyser and polariser are properly constructed, and the two exactly crossed, no radiation will reach the sensitive surface, and the galvanometer will remain unaffected. The field is then said to be dark. But any slight rotation of either polariser or analyser will partially restore the field, and the spot of light will sweep across the scale.

Method of Experiment.

The spark gap 2 m.m. in length is adjusted in a line inclined at 45 deg. to the horizon. The wires of the polariser are placed at right angles to this line. The transmitted beam is then plane polarised, its plane of vibration being inclined at 45 deg. to the horizon. The analyser is now adjusted in a crossed position. On starting the electric vibration, by closing the Ruhmkorff coil circuit, the galvanometer remains unaffected. The crystal to be examined is now interposed with its principal plane vertical.

The Geological Department of India kindly lent me a large number of crystals for examination, for which I have to express my thanks. Out of a large number of experiments, I give below an account of some typical cases.

Rhombohedral System.—1deg. Beryl.—The first piece experimented on was a large crystal of beryl. It is a hexagonal prism with basal planes. The specimen examined has each face 11 × 5cm. The three axes lying in the same plane are inclined at 60deg. to each other, the fourth axis which is also the optical axis, is at right angles to the plane containing the other three. This crystal was optically opaque. On interposing this block with its principal plane vertical, the galvonometer spot flew off the scale. The crystal had thus produced the well-known depolarising action. The crystal was now gradually inclined till its principal plane coincided with the polarising plane of the polariser. There was now no action on the galvanometer. On continuing the rotation the galvanometer at once responded. The spot became quiescent a second time, when the principal plane coincided with the polarisation plane of the analyser. The crystal was now placed with its optic axis parallel to the direction of the incident ray. There was no action on the galvanometer. Rotation of the crystal round this axis did not produce any effect on the galvanometer. The field continued to be dark.

(*2deg. Apatite.*)—This specimen exhibited decided double refraction. (*3deg. Nemalite.*)—This is a fibrous variety of brucite. This specimen exhibited a very strong depolarisation effect. It also exhibited certain interesting peculiarities which will form the subject of a future communication. (*Rhombic system.*)—A large piece of barytes was found strongly double refracting. (*Triclinic system.*)—Microcline, a greenish blue crystal of the double oblique type, exhibited polarisation effect to a remarkable degree. (*Regular system.*)—A large crystal of rock salt was taken. This, as was expected, did not produce any effect.

Having satisfied myself of the fact that systems of crystals other than regular, produce double refraction and consequent polarisation of electrical ray, I tried the action of electric radiation on crystals ordinarily used in optical experiments. I got a fairly large piece of black tourmaline. On interposing this with its plane vertical, there was prompt movement of the spot of light. There was no action on the galvanometer, when the principal plane coincided with the plaue of polarisation of either the polariser or analyser. With ordinary light a piece of tourmaline of sufficient thickness absorbs the ordinary, but transmits the extraordinary ray. With the piece of tourmaline used in the last experiment I found both the rays transmitted, but, it seemed to me, with unequal intensities. In other words, one ray suffers greater absorbtion than the other. It seems probable that with greater thickness of crystal one ray would be completely absorbed. I found other crystals behaving more or less in the same way. I reserve for another communication particulars of experiments bearing on this subject.

Lastly I tried an experiment with a crystal of Iceland spar, taken out of a polarising apparatus. With this I got distinct depolarising action.

The above results, with the exception of the last, were obtained with uncut specimens. Their faces were often rough and irregular. Better results, were they needed, could no doubt be obtained by judicious cutting and polishing the faces.

Summary.

It will thus be seen that crystals which do not belong to the regular system polarise the electric ray, just in the same way as they do a ray of ordinary light. Theoretically all crystals, with the exception of those belonging to the regular system, ought to polarise light. But this could not be verified in the case of crystals opaque to light. There is no such difficulty with electric rays, for all crystals are transparent to them. As a matter of fact, all the above experiments, with one exception, were performed with specimens opaque to light.

ON DOUBLE REFRACTION OF THE ELECTRIC RAY BY A STRAINED DIELECTRIC.*

BY PROF. J. C. BOSE, B.A., B.SC.

The following investigations were undertaken to find whether a dielectric becomes double-refracting to the electric ray when the substance is subjected to a molecular stress by unequal expansion due to heat, or is mechanically compressed. The electric polarisation apparatus, previously described (see page 289, *ante*), was used for this experiment. The analyser and the polariser were crossed, each being inclined at 45deg. to the horizon. The strained substance was then introduced between the crossed analyser and polariser :—

Effect due to Unequal Expansion.—I cast a rectangular piece of paraffin, and placed it, while still hot, in a freezing mixture. The surface was thus chilled. On interposing this between the polariser and the analyser, the galvanometer spot was at once deflected, proving the double-refracting nature of the strained paraffin. The piece was cast six months ago. It has retained its unannealed property even now.

* From the *Journal* of the Asiatic Society of Bengal.

Digitized by Google

Effect due to Compression.—It appeared to me that stratified rocks, which, from the nature of their formations, were subjected to great pressures, would serve well for the purpose of my experiment. My anticipations were verified, as the following experiments will show: I took a cube of sandstone, about 5cm. on each side, and held it between the polariser and the analyser, *with the plane of stratification vertical* and parallel to the direction of the ray. The galvanometer at once responded. I then rotated the piece of rock, and adjusted it with its *plane of stratification parallel to the vibration plane of the polariser. There was now no depolarisation effect*, the galvanometer remained unaffected. On further rotation in the same direction, the depolarisation effect reappeared, to disappear again, when the plane of stratification was made parallel to the vibration plane of the analyser.

I repeated this experiment with many other rocks with the same result.

ON A NEW ELECTRO-POLARISCOPE.*

BY PROF. J. C. BOSE, B.A., B.SC.

In a Paper read before the Asiatic Society of Bengal on "Polarisation of Electric Rays" in May last (see page 289 *ante*) I gave an account of some experiments which showed that crystals which do not belong to the regular system, produce double refraction of the electric ray; and that the refracted beams are plane polarised. Among the numerous crystals examined, I found nemalite, a fibrous variety of brucite, polarising the transmitted beam. The crystal also possesses the remarkable property of extinguishing, more or less, one ray and transmitting the other. A piece of tourmaline also produces the same effect, though to a less extent.

I interposed a piece of nemalite between the crossed electric polariser and analyser. In certain positions of the crystal, the radiation was restored. I then superposed a piece of tourmaline on the nemalite, the two pieces being parallel. The electric ray was now found quenched. If the vibration plane of the transmitted ray in tourmaline is parallel to the length, the vibration plane of nemalite would appear from this experiment to be perpendicular to the length. This was verified by crossing the interposed crystals. The vibration planes are then parallel and the electric ray was found transmitted through both.

I found many crystals of a fibrous nature, exhibiting this property of transmitting the ordinary and the extraordinary rays with unequal intensities. It is thus possible to quench one of the two rays by taking a crystal of sufficient thickness. Serpentine exhibits this property to a marked degree. Different varieties of satin spar are also very effective.

I next tried to construct a polariscope for the electric ray. My first attempt in this direction was to get rid of one of the two rays by total reflection. Calc spar could be used for this purpose; a piece of beryl when properly cut would act still more efficiently. But crystals like nemalite offered greater facilities of construction as one of the two rays is absorbed by the crystal itself. The polariser and the analyser may thus be made of nemalite, tourmaline or serpentine. To ensure a complete polarisation in one plane, a compound polariser could be made by crossing the tourmaline and the nemalite.

The above-mentioned crystals, none of which were very perfect, were kindly lent to me by the authorities of the geological department. I mounted them on temporary supports, and obtained with them satisfactory results. As none of the above crystals can be bought in India, I have to wait for a supply from dealers in Europe. These crystals, when properly cut and mounted, will, I expect, prove to be very efficient polarisers.

In the meantime I have been experimenting with other substances more easily accessible. I discovered that human hair polarises the electric ray. Wool and silk are also good polarisers. One of the most efficient substances for the purpose of polarisation is common jute. I cut fibres of this material 5cm. in length, and built with it a cube with all the fibres parallel. The cube was afterwards mounted in a tube. Two such cells may be used, one as the polariser, and the other as the analyser. The complete polarisation apparatus consists of a radiator emitting electric rays of short wave-length, an analyser and polariser, and a receiver for detecting the radiation. I give below an account of the improved apparatus.

The Radiator.

The electric sparks are produced between two small brass beads and an interposed gilt metallic sphere (*see* Fig. 1). This arrangement, as was shown by Prof. Lodge, produces oscillatory discharge, and the discharge is not much affected by the nature of the surface. In the centre of an ebonite piece is fixed a gilt brass ball 1cm. in diameter. Two jointed electrodes carry two beads at their ends; the distance between the beads and the interposed ball can thus be adjusted. This is a matter of importance, as the receiver does not properly respond when the spark length is too large. The metallic ball may be turned round to expose a fresh surface. The two electrodes press against two springs in connection with an electric machine. The electric generator may be an influence machine, enclosed in a metallic box. I found considerable difficulty in working such a machine in the excessively damp climate of Calcutta. I got over the difficulty by making a Voss machine with ebonite. The machine is enclosed in a metallic box, with an inlet pipe at the top and an exit pipe at the bottom. Air is blown through a calcium chloride tube by means of bellows; the air may be slightly warmed. By working the bellows for a minute or two all moisture is expelled. The tubes may now be closed; the machine will now work satisfactorily for hours even on a most rainy day.

A small Ruhmkorff coil offers some special advantages. It occupies a smaller space, and is easily worked when the modifications mentioned below are introduced. I have discarded the use of the usual vibrating interrupter. The interrupter often fails to produce oscillatory discharge; the sparking balls are worn out by long-continued action, and the battery power becomes unsteady. A single flash of radiation is all that is required. This can be easily obtained by a single sudden break at the primary current; very little battery power is used, and the sparking balls are little affected. In the modified coil there are two condensers and two keys. When the current through the primary is kept flowing always in the same direction the discharge after a time becomes irregular. By alternately pulling the two strings in connection with the two keys the current may be sent in one direction or the other. The keys are provided with springs for the break to be sudden. Instead of two condensers, a single condenser and a reversing key may be used. But for various reasons the arrangement mentioned above is the best.

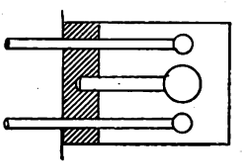


Fig. 1.

The Analyser and the Polariser.

Three different kinds of polarisers may be used:—

(1). *The Jute Polariser.*—I find some difficulty in keeping the fibres accurately parallel, and the transmitted radiation is not, therefore, completely polarised. The absorption of one of the two rays is not complete unless a polarising cell with a great thickness is employed. I am constructing a second pair of cells which will, I expect, be more efficient.

(2). *The Nemalite Polariser.*—A thickness of about 5cm. would produce a fairly complete polarisation.

(3). *Wire-grating Polariser.*—Copper wire about 2mm. in diameter is carefully wound round a thin piece of mica, and the mica immersed in melted paraffin. The wires are thus permanently fixed. There are about 25 wires in 1cm. Four circular pieces are cut out of the grating. Two of these are fixed parallel at the two ends of a tube 5cm. long and 5cm. in diameter. The polariser and the analyser thus made are very efficient.

The Receiver.

I find the following modified form of the "coherer" possessing very great sensitiveness. It has the additional advantage of not losing its sensitiveness:—In a circular piece of ebonite depressions are cut out for the reception of coiled steel springs of a small diameter (*see* Fig. 2). A brass piece slides in or out by the action of a screw. The springs may in this way be gradually compressed, with a corresponding diminution of the resistance. By a slight rotation of the screw the galvanometer spot can easily be brought to the false zero point of the scale. The contact points in this arrangement are numerous and the effective surface very large. The resistance of the receiver varies within wide limits. The receiver I use gives the best result when the resistance is reduced to about 4,000 ohms, the corresponding current circulating round

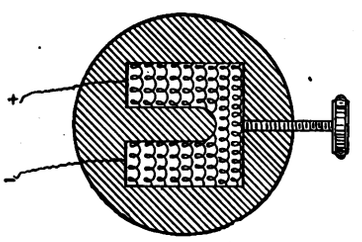

Fig. 2.

* From the *Journal* of the Asiatic Society of Bengal.

Digitized by Google

the circuit is then about $\frac{1}{10000}$ ampere. The incident electric radiation reduces the resistance to about 10 ohms or less. The sudden fluctuation of the current, due to the diminution of the resistance, produces a deflection of the spot of light. I use a couple of these receivers, mounted at the two ends of a tube. One of the receivers, say, one to the left, is put in action by screwing the corresponding screw and unscrewing the other. If by any accident (which hardly ever happens) one receiver becomes less sensitive, the other is brought to the front by turning the receiving tube round the vertical axis.

The galvanometer used is a dead-beat d'Arsonval one. It has a resistance of 300 ohms. I find a small E.M.F. best suited for ordinary experiments. The galvanometer spot may then be adjusted with the greatest ease. By increasing the E.M.F., the sensitiveness is increased till the spot becomes unsteady. By shunting a single Daniell cell with a resistance box, the E.M.F. may be gradually varied. At the beginning an E.M.F. of 1 volt is sufficient. After a time the sensitiveness of the receiver begins to diminish. To increase the sensitiveness, the E.M.F. may be gradually raised to 1 volt. An E.M.F. of about 0·5 volt is best for all-round work. To obtain this I made a copper-iron cell, the iron rod being immersed in a solution of ferric chloride and the zinc in sulphuric acid. This gives a fairly constant E.M.F. Its value is about 0·45 volt.

THERMAL PHENOMENA OF DISCHARGES IN DERIVED CIRCUITS.*

BY PROF. P. CARDANI.

In a note which I published last year,† I had occasion to point out that the problem of the resistance offered to discharges by conductors is not completely solved by Lodge's experiments. In these experiments the chief element was the spark passing between the knobs of a spark gap introduced in one of the derived circuits, and the presence of this spark would necessarily render the phenomenon itself more complicated.

The production of the lateral discharge, as this spark is called, depends essentially upon the manner in which the potential is distributed in the chief circuit at the commencement of the discharge. In the case of continuous constant currents the distribution of the potential simply depends upon the resistance of the circuit; in the case of variable currents we must also take into account the phenomena of self-induction, which influences this distribution in two ways: firstly by the E.M.F.'s. generated, and secondly by changes in the resistance of the conductors.

It is, in fact, well known that continuous constant currents are distributed uniformly throughout the section of the conductors, while in variable currents, such as alternate currents, the phenomena of self-induction condense the current towards the surface into a thinner and thinner stratum as the rate of alternation increases. When these alternations are extremely rapid, as in the discharge of a condenser, the current is crowded into an extremely thin surface layer, which serves to guide it.

If, then, we intend to measure the resistance of a conductor to a discharge from the maximum difference of potential manifested at its ends during the discharge itself; if, in other words, we measure the resistance of a conductor by the total obstruction or impedance which it offers to the discharge, as was done by Lodge, we may measure this resistance by the maximum length of the spark passing in the derived circuit, since this lateral spark depends upon the maximum difference of potential at the points of derivation. But as soon as sparking sets in in the derived circuit the conditions of the phenomenon are changed. As I have shown in the Note above referred to, the spark plays the part of a metallic conductor closing the circuit through the spark gap; the discharge circuit, formerly consisting of a single conductor, is modified by the closing of the derived circuit. In this second period of the discharge the total resistance of the circuit must be different from the initial resistance, and the distribution of the potential must be correspondingly different.

What the true resistance of the conductors in the derived circuits during this second period is, how this resistance is affected by the form and nature of the conductors and of the surrounding dielectric, what the influence of the quantity of electricity concerned or the initial potential is—all these are problems, and not the only ones, that are left unsolved by Lodge's interesting experiments.

The question of derived discharges, therefore, presents itself under two completely different aspects: in one, we suppose but one of the derived circuits is interrupted, and we inquire into the conditions of its being closed by a lateral discharge, and into the behaviour of the conductors which make up the uninterrupted branch; in the other, we suppose that the two derived circuits are continuous, which includes the preceding case from the moment that the lateral discharge closes the spark gap of the derived circuit, and we find, under these entirely different conditions, the resistance opposed to the discharge by each branch circuit.

Under the first aspect the resistance may be measured by the maximum length of the spark in the derived circuit; under the second the resistance of the conductor can only be found *by measuring the thermal effects produced in the derived circuits.*

The Apparatus.

In all the experiments a Voss machine was used with a rotating disc of 92cm. The condenser consisted of 40 jars 40cm. high and 13cm. in diameter, coated with tinfoil. Those 40 condensers were coupled up in four batteries; two of these were insulated and arranged in cascade under the two others whose external coatings were connected with each other and with earth. The inner coatings of the two insulated batteries communicated with the poles of the machine, between the terminals of which sparks 20cm. long could be obtained by using the whole battery.

From the same inner coatings of the insulated batteries was derived the circuit guiding the discharge, and to this circuit, consisting of brass tubes about 1cm. thick, were attached an adjustable spark gap, and the derived circuit in which the thermal effects were to be measured.

The thermometers employed were similar to those used last year.

A platinum wire 0·03cm. in diameter occupied the axis of a glass tube (Fig. 1), and traversed two brass rings, A, B, fixed at the ends of the tube with sealing wax. The platinum wire was well stretched and then soldered to the rings. The ring A bore the bent tube C, to which a forked glass tube, D, was fixed by means of sealing wax. One of the arms, DE, ended in a capillary tube serving for the measurements, and chosen of the best calibre; the other arm, DF, served to fill the whole thermometer with petroleum. For this

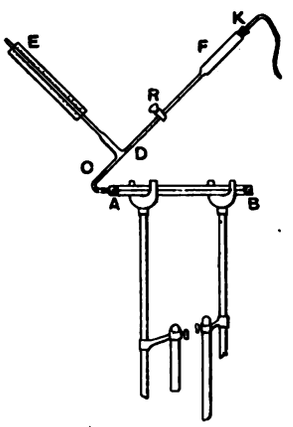

FIG. 1.

purpose there was a tap, R, in the arm, and it ended at the top in a kind of receptacle closed by a cork, K. The latter was traversed by a glass tube attached to an india-rubber tube. Petroleum was introduced into the receptacle, and with judicious compression and aspiration the whole thermometer was filled with petroleum, taking care to drive out all the air. After closing the tap any variation of temperature of the petroleum was indicated by a displacement in the capillary tube. This thermometer also acted as a calorimeter, and measured the amount of heat gained or lost during any interval of time.

To measure the amount of heat developed in the thermometer by a given discharge, the number of degrees was read by which the meniscus of the petroleum was displaced during the minute preceding and following that in which the discharge took place. The mean of these gave the displacement of the meniscus at the time of the experiment by the exchange of heat between the thermometer and its surroundings; adding or subtracting the number thus obtained, accordingly as the thermometer received or lost heat with respect to its surroundings, to or from the number of divisions through which the meniscus travelled in the intermediate time under both influences, the difference or the sum gave the number of divisions corresponding to the heat developed by the discharge. This number, being proportional to the heat developed, could be taken as a measure of the thermal effect due to the discharge.

The Experiments.

Preliminary experiments showed that if one of the branches of the derivation consists of an homogeneous wire, of which one part (that forming the thermometer) is immersed in petroleum and another is open to the air, the quantity of heat is the same as if the whole were immersed in petroleum, and the total quantity of heat developed in the whole of the derived circuit is to that

Nuovo Cimento, 4, 2, p. 69, 1895 (abstract). †*Ibid.*, 3, 36, p. 142, 1894.

Digitized by Google

developed in the thermometer as the total length to the length in the thermometer.

As regards the definition of equal resistances, we may say that two conductors offer equivalent resistances to a certain discharge from a condenser if, when placed successively in one of the branches of a derived circuit, the other remaining constant, they lead to the evolution of the same quantity of heat.

For comparing the resistances of the various conductors I used the method described in the note previously referred to, which I shall now develop in greater detail.

Let a divided circuit be formed by two homogeneous wires, one of constant length L_1 and the other of variable length L_2. This length L_2 can evidently be varied from 0 to ∞, by immediately joining A and B, or by breaking the circuit L_2.

If we determine the quantity of heat developed in L_1 by successively varying the length of L_2, and substitute for L_2 the conductor whose resistance is to be determined, we may from the quantity of heat developed in L_1 determine what length of the conductor first making up L_2 would offer an equivalent resistance.

This principle, which would be evident with ordinary currents, I have thought of sufficient importance to be experimentally proved for the case of discharges.

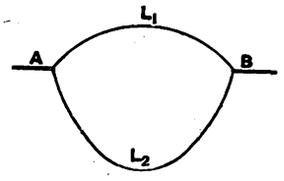

FIG. 2

It is based, in fact, upon the assumption that to every value of heat developed in L_1 there is a corresponding determinate and *unique* value for the heat developed in L_2. This might not apply to currents for which self-induction assumes a preponderating character to such an extent as to render the laws of propagation of these currents in conductors entirely different from those governing the propagation of ordinary currents. But experiments (described in detail) prove that the above principle holds good for every kind of discharge. It was also found that variations in the area embraced by the divided circuits do not sensibly influence the thermal phenomena. The phenomena of self-induction always had the effect of apparently shortening the length of L_2.

The final arrangement adopted consisted of an invariable branch containing the thermometer A, 200cm. long, and of a variable branch, which was successively given the lengths 30, 40, 50, 75, 100, 125, 150, 175, and 200cm. With these a very large number of measurements were made, so as to ensure constancy of conditions. The thermometer A was observed every minute. The sparking distance was kept constantly at 2cm. The wires experimented upon were of copper, brass, iron and platinum.

As regards diameters, it appears that the behaviour of the different metals is sensibly the same, and the resistance decreases

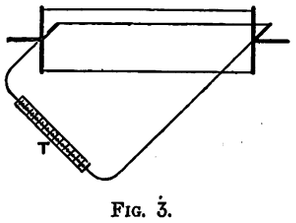

FIG. 3.

gradually as the diameter of the wire increases, but the law of variation is totally different from that for ordinary currents. The results of these thermal experiments distinctly bring out this influence of the diameter, whereas Lodge's and Murani's investigations by the spark length of the lateral discharge show independence of the diameter.

The behaviour of very fine wires is specially interesting. In copper and brass it appears that the resistance of the wires assumes a maximum value for a certain diameter, so that for still smaller values the resistance begins to *decrease*. For iron wires, on the other hand, the variation is regular, at least down to diameters of 0·017cm., the smallest I have tried. The behaviour of platinum is very curious. The resistance at 0·03cm. diameter is practically equal to that at 0·06cm., but the resistance of the wire 0·01cm. thick is exceedingly high compared with all the other wires. Four wires twisted together, with an equivalent diameter of 0·02cm., gave about the same resistance as a wire of 0·03cm. The resistance of very thin platinum wires undoubtedly increases very rapidly as the diameter decreases. I shall probably deal again with the thermal phenomena of very fine wires.

Excluding this case, in which all the metals appear to behave in a special manner, it may be said that the chemical nature of the metals has little effect upon their resistance. Here Lodge's results and mine agree.

The comparison of the results obtained with iron and copper respectively is of special interest. From Lodge's experiments the resistance of iron appeared to be smaller than that of copper. Murani obtained the opposite result, but the differences were small and doubtful, and probably depended upon the special conditions of discharge. The experiments made by Lord Kelvin seemed to prove the decided superiority of copper over iron for conducting the discharges. My results prove that for larger diameters copper and iron wires behave in an identical manner, but that for small diameters iron is more highly conducting than copper. Thus, for the common diameter of 0·136cm., the length of platinum wire giving a resistance equal to that of 100cm. of copper wire is 97·5, while for iron wire it is only 93. These results agree with those obtained by Villari.

Brass shows the same behaviour as copper and iron at larger diameters. At small diameters it has less resistance than copper. Platinum, in the case of the two larger diameters (0·06cm. and 0·03cm.) employed, was a better conductor than any other metal.

A case deserving of special consideration is that of multiple derivation. The experiments were made in the following manner: To the two terminals were fixed two stout conductors at right angles to them (Fig. 3). Each had a length of 10cm., and to these the wires were soldered. Each wire was 100cm. long. Another circuit contained the thermometer A, as before. It was found that these multiple circuits, when the wires are sufficiently far apart, give resistances incomparably smaller than those with single derivations of equivalent section. The resistance varies, in fact, inversely as the number of derivations. Wires twisted together offer a resistance equal to that of a single wire of section equal to that of the sum of the sections.

The results given up to the present refer to the resistance of conductors when all the experimental conditions are left unaltered, such as the form of the conductors, the capacity of the condensers and the sparking distance, and hence also the quantity of electricity; finally, the resistance of the discharge circuit. But in order to draw some conclusions of general import it is necessary to examine in what manner the results are modified by changing those conditions of the experiments. With this I shall deal very shortly in a second part of the present Paper.

PHYSICAL SOCIETY.

At a special general meeting, held on December 13, 1895, Prof. Reinold (Vice-President) in the chair, the resolution with reference to the change in the amount of the life composition fee, passed at the special general meeting held on November 22nd last, was confirmed. The ordinary meeting was then held.

Dr. JOHN SHIELD read a Paper

"On a Mechanical Device for Performing the Temperature Corrections of Barometers."

The form of barometer to which the author has adapted his device is that devised by Dr. Colley; it is intended for general laboratory use, and is capable of being read to within 0·1mm. The barometer tube can be moved in a vertical direction so that the lower meniscus can be adjusted to the zero of the scale. Attached to the barometer tube is a thermometer with a horizontal stem, passing in front of a scale which is fixed to the vertical scale of the barometer. The graduations of this thermometer scale, with the exception of the one passing through the 0°C. mark on the thermometer, are inclined to the vertical, and are so spaced that the reading opposite the end of the mercury column of the thermometer gives directly the correction to be applied to the observed height of the barometer (B_t) in order to obtain the reduced height (B_0). That is, the reading on the thermometer scale gives the value of $B_t(\beta - \gamma)t$, where β and γ are the coefficients of expansion of mercury and of the material of which the barometer scale is composed respectively, and t is the temperature.

Mr. BOYS admired the simple method the author had adopted for plotting the corrections, and said he always felt that the trouble involved in applying small corrections ought, if possible, to be avoided, or the corrections would often be omitted.

Mr. APPLEYARD advised the placing of the bulb of the thermometer within the barometer tube.

Dr. SHIELD, in his reply, said as the barometer was only intended to read to 0·1mm., the placing of the thermometer within the tube did not appear necessary.

A Paper by Prof. RÜCKER, on

"The Existence of Vertical Earth-Air Electric Currents in the United Kingdom,"

was, in the absence of the author, read by Mr. KAY.

Digitized by Google

In a Paper read before the British Association at Oxford, Dr. Schmidt stated that he had expanded the components of the earth's magnetic force in series, and had deduced expressions, two of which give the magnetic potential on the surface of the earth, in so far as it depends on (1) internal and (2) external forces. "The third series represents that part of the magnetic forces which cannot be expressed in terms of a potential, but must be due to electric currents traversing the earth's surface." Dr. Schmidt concluded that such currents amount on the average to about 0·1 ampere per square kilometre. The author has tested this conclusion, drawn from the state of the earth as a whole, by means of an examination of the line integral of the magnetic force taken round a re-entrant circuit taken in the United Kingdom. The necessary data have been obtained from the results of the magnetic surveys for the epochs 1886 and 1891, carried out by the author and Dr. Thorpe. Two circuits, called the α and β circuits, were selected, having their greatest extension N. and S. and E. and W. respectively. The work done by a unit magnetic pole on traversing these circuits was calculated for the epoch 1886 by means of the terrestrial lines found for that date, and also for the epoch 1891 by means (1) of the same lines when due allowance was made for secular change, and (2) of the independent set of lines found by aid of the 1891 survey. The same calculation was made for a third circuit (γ) using instead of the calculated terrestial lines the true values of the forces and declinations as deduced from the nearest stations. The following table gives the results in amperes per square kilometre :—

——	α	β	γ
1886	−0·026	−0·004	...
1891 (1)	+0·001	−0·005	...
1891 (2)	...	...	−0·008

From these figures the author concludes that there is not, in the United Kingdom at any rate, a vertical current amounting on the average to 0·1 ampere per square kilometre.

Mr. WATSON said a few words on the difficulty experienced in determining the line integral in South Wales due to the presence of closed curves.

The Society then adjourned till January 24th, 1896.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December 13, 1895.*

Fundamental Trolley Patent Sustained.—A Federal Court has sustained the fundamental Van Depoele patent on the under-running electric railway patent, the application for which was filed in 1887 and the patent granted as recently as 1893. This decision, if sustained by the higher Court to which it will be appealed, will introduce serious complications in the electric railway industry, as it recognises the fundamental claims of the patent in suit, which appear to cover every possible form of under-running trolley. The opinion of the Court admits that numerous forms of trolleys had early been devised for railway train signalling and lighting purposes, eleven of which were for under-running trolleys; also, that the "third-track trolleys" of Edison and Daft, which antedate the Van Depoele patent in suit, are devices of substantially the same construction as the latter. The argument of the defence that it was only necessary to turn the Daft and Edison devices over in order to obtain the Van Depoele invention is met by the Court with the answer that these devices would not have possessed the vital feature of providing capacity for universal movement, and it is upon this consideration that the patent is sustained. The Court, in fact, held that when Van Depoele reversed the trolley of Daft and Edison and added capacity for lateral and vertical motion, and thus "disclosed to the public a practically operative means, such as the whole world had heretofore sought in vain, he made an invention within all the rules applicable to this question." The several elements of this addition were the long "upwardly spring-pressed" pole, its pivotal support and lateral hinge, which, in the eyes of the Court, caused the electric railway to pass at a bound from an experimental and impracticable state to that of a completed art.

An Electric Elevated Railway in a Snowstorm.—During a recent severe snowstorm in Chicago traffic on all of the street surface roads in the city—trolley, horse and cable—was suspended, while the electric elevated road continued in full operation, carrying not only its usual quota of passengers, but most of those left unserved by the surface lines.

Trolley Trouble in Philadelphia.—The Quaker city is stirred up by the recent action of the street railway monopoly of that place in abolishing transfers on certain portions of its system. The traction interests some months ago procured the passage of an Act—by equivocal means, it is charged—enabling the consolidation of the various important roads of Philadelphia into a single company, and recently parts of the transfer system, in force before the consolidation, were abolished. A mass meeting, at which there was an attendance of 5,000, held to protest against this action, was addressed by an ex-Governor and other leading citizens, and sweeping denunciations were made of the street railway monopoly and of the legislative action which placed the people in its power. It was proposed, if the Traction Company did not come to terms, to procure the construction of elevated railways and agitate for the purchase and operation by the Municipality of the city surface roads. It is not at all probable, however, that this latter will be done in any event, as the knowledge of the political corruption experienced in connection with the municipal gas plant will deter such action.

CORRESPONDENCE.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At the annual general meeting of the Institution of Electrical Engineers, held at Great George-street on Thursday last, I addressed the members and proposed a resolution which appeared to meet with nearly unanimous approval.

From the remarks of one or two speakers it became evident that the resolution was not clearly understood, and as some time will elapse before the issue of the *Journal*, I think it desirable, in order to prevent misconception, to give you for publication an exact copy of the words used.

In opening the discussion I said (reading from a written memorandum):—

"I observe with regret that the Council, in their Annual Report, have not asked the Institution to grant them increased facilities for obtaining the opinions and advice of members on matters affecting the welfare of the Institution."

And in concluding I proposed the following resolution:—

"That this meeting considers it desirable to form a Committee to represent the views of the members in consultation with the Council, and such Committee is hereby constituted with the following members:—(London) A. A. C. Swinton, E. Manville, R. P. Sellon; (Liverpool) A. B. Holmes; (Manchester) W. P. J. Fawcus; (Newcastle) A. W. Heaviside; (Glasgow) H. A. Mavor; (Birmingham) J. C. Vaudrey, with power to add to their number."

The wording of the above resolution was defective in that it did not describe the proposed Committee as temporary. I may also state that there was no intention to invest the Committee with legal powers. The honorary solicitor ruled that the resolution was out of order, and the President recommended that an extraordinary meeting of the members should be specially called to discuss it.

Personally I am sorry that this course has been recommended, as it will tend to give the discussion a more belligerent tone than I had any intention of imparting to it. There is no question at issue between the members and the Council, and so far as my knowledge extends the members are not only satisfied with, but also proud of their Council. There is, however, a strong feeling that the Council is hampered in interpreting the wishes of the Institution by the existing rules, which do not provide any simple and constitutional means of communication between the Council and the body of members. This defect in the constitution is not a mere creation of the imagination, but a fact attested by actual experience. At the same time I imagine it is a defect which the Council will be

Digitized by Google

as eager as the members to see remedied. An extraordinary general meeting is at best a clumsy contrivance and ought to be resorted to in extreme cases only, or for the purpose of altering the rules.—Yours, &c., JOHN S. RAWORTH.

December 16, 1895.

[We regret that, owing to non-receipt of corrected proof, this letter was not inserted last week when editorial reference was made to it.—Ed. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Some years ago I found myself in identically the same position as Mr. Raworth was at the last annual meeting, and although the proposals I wished to make were, I think, calculated to enhance the usefulness of the Institution, I refrained from getting 10 members to ask for an extraordinary meeting. Put it as we will, an extraordinary meeting convened at the request of members has an appearance of hostility to the Council, which none of us want. I venture, however, to express the hope that the Council will themselves appoint a Committee for the purpose of considering whether a revision of the rules has not, by reason of the vast increase of members, become advisable. If the Committee arrive at the conclusion that the rules may be improved upon, the proposed revision could be circulated amongst the members, and the Council themselves might call an extraordinary meeting.

Having said so much, perhaps one ought to suggest one or two alterations that seem worth consideration. Do we not use up our presidents too quickly? Why should they not keep office for two years? As to qualification, the second rule is, to say the least, vague. Is it not an anomaly that the senior vice-president should be entitled in the absence of the president to preside at a Council meeting, and yet may by some not be considered eligible for the office of president? And last, though not least, surely in a large institution such as ours has become there ought to be some legitimate and recognised method by which members may at the annual meeting bring forward proposals for the benefit of the Institution without being placed in the invidious position of being obliged to move an amendment on the report of the Council. —Yours, &c., S. FLOOD-PAGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It does not appear to be disputed by anyone that, owing partly to the rapid growth of electrical industries in several directions, and partly to progress in people's ideas as to the functions and scope of representative professional institutions, the methods, organisation and procedure of the Institution of Electrical Engineers have fallen somewhat behind the times, and are no longer adequate to represent properly either the aims or the requirements of the profession.

That under these circumstances there should be discontent and agitation is only natural. That, in the onset, this agitation should be obscure in its origin and indefinite in its objects almost absolutely follows, when the diversity of the interests depending on electricity is considered. For discontent and dissatisfaction to grow would be very undesirable, while there is every reason for trying to satisfy those aspirations of members which are legitimate, and for endeavouring to make the Institution as representative, useful and up-to-date an organisation as possible. There is therefore no reason for either haste or secrecy, nor for anticipation that the existing Council of the Institution would meet any well-considered and influentially-backed suggestions in other than a friendly spirit. It is therefore most desirable that any schemes of reform or alteration should be brought forward openly, be debated carefully, and should be finally put forward only if there is a considerable body of opinion in favour of them.

Granted that a representative meeting of members were called, and that they, after discussion, appointed a committee to consider the matter, it may be asked what form the suggestions of that committee should take.

Before going into this it appears important to take into consideration what is the position of the Institution and its members at present. It is obvious that the members are firstly divided into broad groups comprising telegraphy, telephony, electric light and power, and electro-chemistry. Each of these groups again comprises consulting engineers, manufacturers, contractors, executive engineers, besides educationalists and some smaller sub-divisions. No argument is needed to show that there is much diversity of aim and interest in the main groups alone, not to speak of their sub-divisions. It is also pretty clear that these groups will tend to differentiate still further in time. It is also manifest that all these groups of industries are increasing in importance and advancing at a rapid rate.

This heterogeneous mass of members is represented at present by a Council consisting of 13 *ex-officio* past-presidents (with full voting powers), 1 president, 4 vice-presidents, 12 full members of Council, 3 associate members of Council: a total of 33 voting members of Council.

Of these 33 voting members 14 are perpetual, and 4 nearly perpetual, so that the balance of voting power always lies with the perpetual members; besides this, the latter have all the moral advantage which continuity gives. The 3 associate members, of course, do not count for much, their position being a semi-honorary one.

The real representation of the body of members, numbering 1,700, is therefore confined to the ordinary members of Council, who only amount to 14, and of whom only three are, except in case of vacancies, elected annually. The new blood which can thus be introduced is only 10 per cent. of the Council annually, even if no members are asked to serve a second period, which is often the case. When it is further recollected that out of the four places, which is about the number vacant annually, and open to the introduction of new blood, places must be found for representatives of the army, navy, occasionally of the law, and sometimes of electrical finance, it needs no argument to show how ridiculously small must be the representation of that vast body of men who, not to include telephony and telegraphy, have been pouring into the electrical industry proper during the last 10 or 12 years at the rate of many hundreds a year. With the present constitution and at the present rate of progress, which bids fair to be maintained at any rate for some years, the representation of this great and increasingly influential body of men must become more and more inadequate unless something is soon done to put matters on a more up-to-date footing.

The question then becomes what line these reforms should take. This is evidently very debatable, but it seems to me that something on the lines of the following suggestions would meet the difficulty fairly.

In addition to the present Council, which might remain as it is, three permanent committees might be appointed—one to represent Telegraphy and Telephony, one for Electric Light and Power, and one for Electro-chemistry. Each of these committees should consist of about six members, under the presidency of a senior member of Council or Vice-President. Three members of each committee might retire annually, and three new ones be elected annually by the Society. These three committees could make any recommendations they pleased to the Council through their President, and such recommendations might be in writing and could be published in the *Journal*, together with the Council's replies, favourable or otherwise, in which way members would have some idea of what was going on. These committees need have no executive power except through the Council; but they would be in much closer relations with the particular group they represented than the Council are now, and would know the requirements of their constituents much better, and as at least nine new men would be needed each year in addition to those now required, it would offer an opening for the infusion of sufficient new blood, while each branch of the electrical industry would feel that there was a body to look specially after their interests. The committees would also form an avenue to the Council.

The above is, of course, a mere outline, but it would appear as if, in some such way as sketched above, adequate representation of all the groups of members could be secured for some time to come, while the usefulness and progressiveness of the Institution would be much increased, without upsetting existing arrangements.

Digitized by Google

There are, it seems to me, a number of important and pressing questions which the strengthened Council could then deal with, and which would add immensely to the utility of the Institution if properly taken up, besides which its prestige and capacity for promoting the interests and convenience of members would be much increased.—Yours, &c.,

G. L. ADDENBROOKE.

December 21, 1895.

P.S.—At the Royal Photographic Society, the allusion to which so amusingly excited Mr. Campbell Swinton's ire at the general meeting, great benefits have arisen from a scheme of affiliation by which local and provincial societies are kept directly in touch with the senior Institution.

TELEGRAPHY IN LONDON: 1847-1895.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has just been drawn to a paragraph which appears in a contemporary, stating that the new Post Office telegraph station at St. Martin's-le-Grand is the largest establishment of the kind in the world, some 3,000 operators being engaged within its walls.

There can be but few of your readers who will be able to realise, personally, the difference between the result of what the above statement conveys and the status of the electric telegraph in England not quite 50 years ago, when London had *no* telegraph, as we understand it now, just as only about 10 years before that it had *no* railway either. These are two facts within my own ken; for about 60 years ago I played cricket with schoolfellows at Willesden on ground that was soon after appropriated by the London and Birmingham Railway Company for the construction of the first line into the metropolis. I fix this date also by having been present at a meeting between Mr. Ericson (of American "Monitor" fame), then on the staff of surveyors for George Stephenson, and my father, who at that time was building houses in the neighbourhood of the proposed railway route nearer London, on which work had not been commenced.

It was not until 1847 that London had its first telegraph office for the reception of private messages for transmission to other places. I am able to fix this date, too, for, beside having the charge of lines leading to it, I had the responsibility of this first office in addition. I will admit it was not much of a charge after all; but it is just the little it was that I wish to draw your attention to—the object of this letter, in fact.

The first important move in the matter of telegraphs, in this country, took place in the year 1845; and by the beginning of the next year the Trent Valley from Rugby, the "Midlands," the "North Midlands" with Birmingham on the one side and Hull on the other, with Newcastle, and well on to Scotland, were all supplied with the telegraph for railway purposes. Other railways, with the numerous cities and towns on their lines, were soon included in the net; but London was *not* among them until the year 1847. This extension was effected at the cost of the Electric Telegraph Company, on the line of the London and North-Western Railway, in order to afford the metropolis the facility of telegraphing private messages all over the country.

Gutta-percha had not yet made its advent. Imperfect insulation was then the *bête noir* of the telegrapher, so underground wires of any length were not to be thought of. In consequence of this the London telegraph office had of necessity to be situate as near as possible to the Euston Station. For this purpose, then, a house in Seymour-street was secured—the third from the south-eastern corner of the crossing of that thoroughfare with Drummond-street. Here, with only three operators, the business of telegraphing all over Great Britain for a few months was accomplished; and my own part of the duty was easily got through, with the attendance of an hour or two, on two or three days of the week. For succeeding weeks the receipts for messages to all parts did not exceed £30; and even after two or three months' working, little progress was made towards increasing that amount; until at last I was able to congratulate the officers of the Company, at 345, Strand, on my having brought *£35* with me, in my cash box, as the result of *one week's* takings.

But, as if by magic—all at once, the impossible became possible of realisation—*gutta-percha* came to our rescue, and the Seymour-street office was without loss of time abandoned for Founders-court, near the Bank of England. From that moment, as might be expected, the greatest change came over the scene. We see the result of it to-day—a *thousand* operators employed where *one* sufficed then; and a hundred, doubtless, must now be engaged in the work of superintendence—that I was able then to get through in a few hours per week.

If you, Mr. Editor, think this little illustration of what must have been accomplished in telegraphy within the last 50 years, or less, would be interesting to some of your readers, I have great pleasure in placing it, or any part of it, at your service.—Yours, &c.,

J. W. WILKINS.

PRESSURES DANGEROUS TO LIFE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I be permitted to remind Dr. H. Lewis Jones of two deaths from alternating currents which he seems to have overlooked, viz., that of a sailor on board the Czar's yacht "Livadia," and that of a member of the orchestra at Aston Lower Grounds, Birmingham.

If my recollection of these fatalities does not mislead me, they were both caused by alternating-current Gramme machines, used with Jablochkoff candles. Each machine had four circuits, with five lamps on each, so that the pressure on each of the circuits, which were quite independent of one another, was about 250 volts.

Probably Mr. Applegarth could give precise information on these almost forgotten accidents, which occurred some 15 years ago.—Yours, &c.,

T. E. GATEHOUSE.

THE COST OF LIGHTING BY GAS AND BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The two letters referring to the above in your last week's issue will probably have struck many of your readers as being somewhat contradictory. The engineer of the Hastings Gas Company, very justly points out that nothing is gained by rival companies making erroneous statements to damage one another, and the vice-chairman of the same Company follows this up by repeating his original statement, viz., that gas at 8s. per 1,000 cubic ft. is one-third as cheap as electricity at 9d. per unit.

I think that Mr. Botley should have explained (since he now takes objection to some of the arrangements made by Mr. Trotter) that he was invited to be present at these tests to see fair play, but that he declined, his chief reason for doing so apparently being that he failed to understand why such tests were necessary.

Mr. Botley points out that the measurement of illumination is a very different thing to the photometrical examinations of the real value of different descriptions of light, and I am quite willing to admit that it is so, but the question that chiefly interests a customer is, not what is the photometric value of the two lights, but what will be the comparative cost of producing a certain illumination in his premises, whether gas or electricity be used.

Objection is raised to the gas burners tested; we endeavoured to be as fair as possible over these, and so got two local plumbers and gas fitters to lend us a selection of the burners they found from experience to be most generally used in Hastings. As the Sugg burner was a new one, if it was out of order, it shows they are very liable to get so, consequently it would hardly be fair for a practical comparison only to take the results to be obtained from a perfect one.

If the Gas Company, when endeavouring to persuade the Hastings public that electricity was three times as costly as gas, had explained that this statement did not apply to those who used 2½ to 3 watt lamps, or globes with their gas lamps, or flaring batswing burners, or Bray burners, or even Christi-

Digitized by Google

ania burners—unless great care was taken to keep them always in perfect order—those to whom it did refer would have been so few that the Electric Light Company would never have needed to call in Mr. Trotter to their assistance.—Yours, &c., L. Andrews, Engineer and Manager to the

Hastings and St. Leonards Electric Light Company

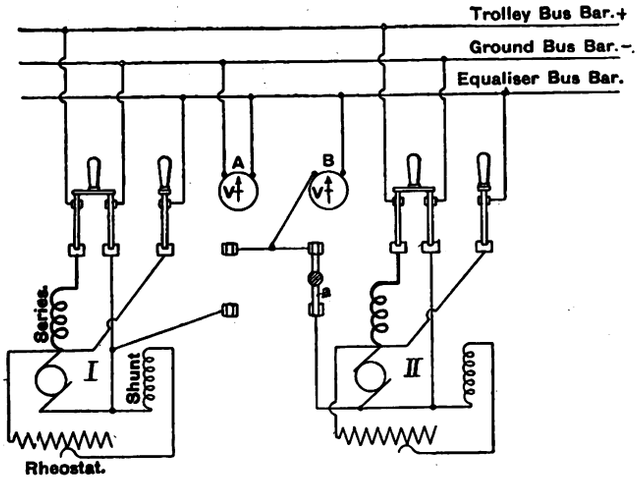
December 18, 1895.

HOW TO THROW ON A RAILWAY GENERATOR.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Referring to the Note, published in your issue of the 13th inst., on "How to Throw on a Railway Generator," I may mention a special switch combination for the purpose of preventing, as far as possible, a railway generator being thrown in circuit by careless operators before the equaliser switch has been closed.

The main double-pole switches and the equaliser switches are connected in the usual way. The voltmeter A is permanently connected with the negative bus bar and the equaliser 'bus bar, while the voltmeter B, on which are taken the readings of the dynamos to be put in circuit, is connected with one pole to the equaliser 'bar, with the other pole to the upper terminals of as many voltmeter switches as there are dynamos in the station. All these voltmeter switches have only one common removable connection bar, *a*, fitted with an insulated handle.



This bar, or knife, is put into the voltmeter contacts of the dynamo to be put in circuit, but, as the voltmeter circuit B is then not yet closed, the operator, in order to take any readings on the instrument, has to close the equaliser switch II. By this simple device there is little chance of the operator forgetting to close the equaliser switch before putting the generator in circuit by means of the main switch.

As there is only one connection knife for all the voltmeter switches, the said device prevents, too, the short-circuiting of generators through these switches, which are generally very dangerous when of the double-pole type.—Yours, &c.,

H. Dubs,

Chief Engineer of the Marseilles Tramways.

THE MICHIGAN MINING SCHOOL DEGREES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Owing to illness I have for some months been absent from Houghton. During that time I was unable to look over the various technical journals, and in consequence I have but just read your issue of August 16th, and its editorial "Graduation in Business." This article entirely misrepresents the Michigan Mining School, but it is so inaccurate it its statement of facts that I have neither the time nor the inclination to answer it in detail. The following extracts will enable those interested to gauge the value of this criticism. "There are numerous subjects, many not connected with mining (*sic*), taught at the Michigan Mining School, and each is worth so many units or fractions of a unit; and the *game—for it is not unlike a species of game*—is to 'pass' in enough units to win a degree. To qualify as a mining engineer at the Michigan Mining School you must pass in 22 full courses, including subjects 20 and 21, *which means that you must get 22 units anyhow you please*, except that *decimal two* of a unit will have to be obtained by studying 'elementary geology,' and *decimal three* of a unit by passing in 'elementary principles of mining.' And then you are a full-blown E.M., and may bore holes in the ground, and put up ricketty machinery, which will presently fall down and kill somebody." The italics are mine.

Consulting the introduction, page 5, of the "Prospectus" from which you quote, you will find that for details concerning methods of instruction, the equipment of the Institution, &c., the reader is referred to the regular school catalogue. Unless you read this catalogue (and your remarks show that you did not), you have no means of judging what degree of proficiency is here required of a student that his work may be accepted. Had you given more study to this aspect of the question, you would not have written, toward the close of your article, "The degree will sink rapidly into discredit and become an object of scorn, if its only basis be a vellum certificate bolstered up by a pile of college note-books, and a three-years course of lectures." A little investigation would have shown you that the basis here referred to exists only in your imagination. As to the value of our degree, allow me to say that up to date there is not a single graduate of this School out of employment, so far as we know. It might further interest you to learn that some of your own leading engineers have investigated the Michigan Mining School more thoroughly than you have yourself. One of our recent graduates was sent here from an English mining town and mining school to get a "degree." He is now employed by one of the largest and most important mining companies in the United States, and when we last heard of him his employers considered him an able and competent engineer.

As to getting "22 units *any way you please*," kindly refer to Prospectus, page 13 (last paragraph), and to page 25 ("Required Studies," *et seq.*), and you will find information to convince you that this statement is wholly inaccurate. The student chooses his *major subject*, and the sequence of studies explained in the paragraphs to which I have just referred you settles at once what ground that student must cover to prepare himself thoroughly for the main subject so chosen; nor has he any power whatever to omit any single preparatory subject essential to the proper prosecution of the advanced work.

Kindly pardon me for calling your attention to the fact that $\frac{2}{5}$ is not equivalent to decimal two, nor is $\frac{3}{5}$ the equivalent of decimal three. I merely mention this to show how little care was taken when gathering the facts upon which your editorial is based.—Yours, &c., Edgar Kidwell.

Houghton, Mich., December 9, 1895.

[It is unnecessary to say that we had no intention of doing the Michigan Mining School an injustice in our interpretation of its system of Elective Studies. The system itself is so elaborate and so unusually complicated that, although we spent a considerable amount of time in the perusal of the pamphlet explaining it, there is perhaps little wonder if we failed to completely grasp all its intricacies. It is gratifying to hear of the genuine and useful work which has been done by this Institution; past work, however, is not necessarily a guarantee that the new "elective" system of granting degrees possesses peculiar merit. In regard to the relation between *decimal two* and $\frac{2}{5}$, &c., we have no recollection of having implied their equality. To the best of our recollection of the matter, "elementary geology" is awarded one-fifth of a unit, which is "decimal two."—Ed. *E.*]

University College, Nottingham.—The Committee of this College invite applications for the post of Demonstrator in Electrical Engineering from candidates who have good technical knowledge, which must include electrical testing and the management of dynamos, alternators, motors, transformers, arc lamps and secondary cells, and the design and construction of electrical instruments and machines. Some further particulars are given in the advertisement columns of the present issue.

Digitized by Google

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is in active preparation, and orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. The usual circulars, &c., are now being sent out. Full particulars post free on application.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper, price 6d.

TENDERS INVITED.—The Gas Committee of the County Borough of Salford invite tenders for the supply of 1¼ miles of concentric cable. Some particulars will be found in our advertisement columns, and tenders must be in by 5 p.m. on January 2nd.

——— The Guardians of St. Luke, Chelsea, require tenders for the fitting up of an electrical wiring installation, including fittings, in the Chelsea Infirmary extension, Cale-street, Chelsea. Tenders by noon 31st instant.

——— Messrs. Arnott and Co. (Limited) invite tenders for an electric light and power installation at their new premises in Henry and Princes-streets, Dublin. Tenders by 8th prox.

TENDERS ACCEPTED.—The Leyton District Council have received the following tenders for the supply of plant and apparatus, the erection of buildings, &c., in connection with their electric lighting scheme:—

Buildings, Machinery, Foundations, &c.

Rous, H. R., Grays, Essex (*accepted*)	£2,394	14	7

Gas Producing Plant.

Dowson Economic Gas and Power Co., London (*accepted*)	854	15	0

Dynamos, Switchboards, Transformers, Wiring Buildings, &c.

Electric Construction Company (*accepted*)	1,330	7	2
Holmes (J. H.) and Co. (Newcastle-on-Tyne)	1,726	10	0
Johnson and Phillips	1,602	6	0
Thames Ironworks and Shipbuilding Company	1,502	7	6
Brush Company	1,492	0	6
India Rubber Company	1,479	8	2
Siemens Bros. and Co.	1,478	7	0
Laurence, Scott and Co. (Norwich)	1,411	5	0
Wigston Electrical Engineering Company	1,371	6	0
Crompton and Co. (Limited)	1,339	12	0
Nalder and Harrison Construction Syndicate	1,163	0	6

(Remainder of London.)

Storage Batteries and Cable Connections.

A. B. Pescatore, Manchester (*accepted*)	£743	4	6
Headland's Patent Storage Battery Company	1,113	0	0
Johnson and Phillips	1,082	10	0
Epstein Electric Accumulator Company	844	16	1
Conze and Simon	818	16	0
Electrical Power Storage Company	754	5	10
Pritchetts and Gold	632	16	6

Mains.

Siemens Bros. and Co. (*accepted*)	£8,996	1	6
India Rubber Company	11,354	15	10
Henley's (W. T.) Telegraph Works Company	10,286	11	10
Wigston Electrical Engineering Company	9,920	13	4
Glover (W. T.) and Co. (Salford)	9,646	5	1
British Insulated Wire Company (Prescot)	9,380	15	5
Fowler-Waring Cables Company	9,295	16	2
Callender Company	9,240	14	1

(Remainder of London.)

BUSINESS CHANGES.—The London address of Messrs. Dorman and Smith will be changed after January 1st from 11, Grocers' Hall-court, E.C., to 94, Charing Cross-road, W.C., the firm's telegraphic address, "Prefix London," remaining as before.

EXTENSION OF WORKS.—The Electric Construction Company propose to make some important additions to their existing works at Bushbury. The work of clearing the site of the new building has already commenced.

DIVIDEND.—The dividend declared by the trustees for the estate of Messrs. Brordning and Gardner, lately trading as electrical engineers, of George-street, Edinburgh, is now declared, and will be paid any day after the 26th inst. The dividend is the first and final of 2s. 2d. in the £.

APPOINTMENTS.—Messrs. P. R. Jackson and Co. (Limited), engineers, of the Salford Rolling Mills, Manchester, have just made the following additions to their staff:—Mr. W. H. Ravenshaw, A.M.Inst.C.E. (of Booth and Ravenshaw, 110, Cannon-street, London, E.C.) as consulting electrical engineer; Mr. E. J. Blandy, A.M.Inst.C.E., as representative in South Wales and the Midland Counties; Mr. A. M. Shepherd, of 32, Albany-road, Ealing, W., as representative in London and Southern Counties; Mr. W. F. Jones (late of Easton, Anderson and Goolden) as assistant engineer; and Mr. Felix J. Howitt (late of the Norwich Electricity Supply Company) as assistant electrical engineer.

——— Mr. S. A. James has been appointed chief superintendent of the Telegraph Department at Glasgow, *vice* Mr. G. H. Midgley, who has resigned. Mr. James has acted on behalf of Mr. Midgley for some time past.

ELMORE COPPER MANUFACTURES.—In the report issued by the Directors of Elmore's Wire Manufacturing Company, it is stated that after an exhaustive series of comparative tests the Board of Trade has sanctioned the use of Elmore's copper pipes in passenger steamers built under their survey.

ALUMINIUM.—Another use to which aluminium readily lends itself is shown by a neatly-printed complimentary card received from the British Aluminium Company (Limited), of Victoria-street, S.W., which is very effectively printed in two colours. Both sides are printed, and although the sheet is very thin the print does not at all show through. The novelty of the thing and its extreme lightness should cause a considerable demand for this material for business cards.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—We learn that Mr. G. Carnaby Harrower, of College Hill-chambers, E.C., has resigned his position as manager in London of this Company. The offices of the Company are now at Mansion House-chambers, Queen Victoria-street, E.C.

CALENDARS.—Messrs. Engelbert and Co., of Bishopsgate-street, E.C., send a useful hanging calendar, copies of which the firm will be pleased to supply free on request.

MASCHINENBAU AKTIEN-GESELLSCHAFT NÜRNBERG (VORMALS KLETT).—This old-established and well-known firm send us a copy of the *Technische Revue* of November 24th which contains a description and illustrated particulars of some of their manufactures. The firm was established in 1837 by the late Herr Johann Friedrich Klett, and at the present time over 3,000 hands are employed at the works in Nürnberg and at the branch at Gustavsburg bei Mainz. The Company's manufactures include cars for electric tramways and railways; steam, gas and oil engines; boilers, pumps, electric, hydraulic and hand cranes and lifts, refrigerating machinery, material testing machinery, &c. In the article views are given of the bridge over the North Sea and Baltic Canal at Grünenthal, which is claimed to be the highest bridge in Europe, and has a span of 156 metres, and of the great central railway station at Munich, which are fine examples of this firm's workmanship. The gas and steam engine departments of the Company's works are very extensive, special attention being given to engines of both types for electric lighting work.

Digitized by Google

DIARIES.—The publishers of the *Indian and Eastern Engineer* send a copy of the Diary and Reference Book issued in connection with that journal. The book contains a quantity of very useful information for the engineering trades, particularly in connection with business with India. A complete list of the Indian Government officials, a table of English values of foreign weights and measures, in addition to specialist engineering matter, should make the book of much value to contractors and others. The Diary and Reference Book is free to subscribers to the paper.——We have received from the Brush Electrical Engineering Company a handy diary suitable for the pocket as this actually exists in most people's coats.

PRICE LISTS.—Messrs. W. H. Allen, Sons and Co. send us copies of two new price lists of their direct-coupled steam engine and dynamo sets. These sets have been so extensively used for ship lighting for the Admiralty and mercantile services that they are too well known to require any lengthy comment from us. Both in design and construction they leave little if anything to be desired, and they are well adapted to the class of work for which they are specially constructed.

CALVERTS' MECHANICS' ALMANACK.—The twenty-third year of publication of this annual, which is edited by the editor of the *Textile Recorder*, brings before the public a very handy and useful little pamphlet almanack. The calendar part is filled with dates of important and interesting engineering and other events; general and scientific information of a useful nature is sprinkled profusely over the 64 pages, and the latter part of the pamphlet is devoted to practical hints, rules and data specially serviceable to mechanics and engineers. The published price of the Almanack is 4d.

CONCENTRIC WIRING.—We have received a copy of a new list of concentric wiring, materials, &c., from Messrs. Sharp and Kent. The list embraces a complete system of switches, fuses, sockets and lamps for use with earthed conductors. Messrs. Sharp and Kent have had considerable experience in this method of wiring, having installed something like 5,000 lights in the past twelve months on the system.

ASYLUM LIGHTING.—The expenditure of a sum of £2,600 has been sanctioned for the purpose of introducing the electric light into Purdysburn House, the Belfast district lunatic asylum.

AUDIT OF SUPPLY COMPANIES' ACCOUNTS.—The following important correspondence has been sent to *The Times*. The matter is of considerable moment for electric supply companies, as the abolition of the apparently unnecessary second audit has been, we understand, under very general consideration:—

SIR: The attention of the Council of this Institute was directed to an advertisement which appeared in *The Times* of November 29th last giving notice that at a general meeting of an electric light supply corporation a proposal would be made:—

"That in order to save the trouble and expense of a double yearly audit, it be and is hereby resolved that the auditor appointed by the Board of Trade for the official audit should also act as the shareholders' auditor."

I was instructed to write to the Board of Trade and to ask whether in their opinion an official auditor of that Board is at liberty to accept the appointment of shareholders' auditor in an electric light company, and to point out that the functions of an official auditor and a shareholders' auditor are not only different, but to some extent conflicting. In reply I have received a letter from the Board, a copy of which I enclose, and which I shall be glad if you will publish in your next issue.—I am, Sir, your obedient servant, W. G. HOWGRAVE, Secretary.

Institute of Chartered Accountants in England and Wales.

Board of Trade (Railway Department), 7, Whitehall-gardens, London, S.W., December 18, 1895.

Electric Lighting Acts, 1882 to 1890.

SIR: With reference to your letter of the 5th inst. calling the attention of this Department to a resolution dealing with the question of the audit of the accounts of the . . . which it is proposed to submit to the next general meeting of the shareholders of the . . . , I am directed by the Board of Trade to state that they hold it to be outside the province of the auditor appointed by them under the terms of the Provisional Order granted to the Company to act as auditor on behalf of the shareholders.

I am further to state that the audit conducted by this auditor is of a different character to that of a shareholders' audit, and has in view different objects, and it appears to the Board of Trade that it rests with the Company to determine whether they are acting legally if they entirely dispense with the audit contemplated by the Companies Acts.—I am, Sir, your obedient servant, FRANCIS J. S. HOPWOOD.

The Secretary to the Institute of Chartered Accountants, Moorgate-place, E.C.

BAKER-STREET AND WATERLOO RAILWAY COMPANY.—In the Bill which this Company intend to introduce in the next Session of Parliament powers are sought to abandon part of their authorised railway from New-street (Upper Baker-street) to Langham-place, and to substitute a railway to start at the eastern end of Upper Baker-street and terminating at the western end of Melcombe-place. Powers are also sought for extending the borrowing periods beyond March 28, 1896, and March 28, 1898, to acquire lands and to construct the railways authorised in their 1893 Act in three sections, each to be formed into a separate undertaking with separate capital and borrowing powers. The Bill also contains a provision for entering into working arrangements with the London and South-Western, the Manchester, Sheffield and Lincolnshire, the Metropolitan, and the Waterloo and City Railways, and for paying interest out of capital during construction.

BRADFORD.—According to the Corporation accounts for 1894-95, which have just been issued by the borough accountant, the gross income from the electricity department during the period under review was £11,737 and the expenditure £5,773, leaving a gross profit of £5,964. After deducting interest and sinking fund (£4,095), and allowing £1,063 for depreciation, there was a net profit of £806 on the year's working.——The Gas and Electricity Committee have decided to recommend the Town Council to purchase a site for the erection of new electricity works.

BRIDGWATER.—The Town Council have appointed a sub-committee to consider the question of the electric lighting of the town, and also to negotiate with the local gas company for the purchase of their works.

BRIGHTON.—At the meeting of the Town Council last week the Lighting Committee's report was discussed. This report recommends that—

"Notice be given to the Brighton and Hove General Gas Company of the intention of the Council to determine on June 30th next the existing agreement for the lighting of the public lamps in the Borough, and that the Town Clerk be instructed to negotiate with the Company for a new agreement, reserving power to the Council to discontinue the lighting of all or any of the lamps on one month's notice expiring at any time."

Councillor Stafford (the Chairman of the Committee), moved the adoption of the report, and said that the Committee were anxious to have a new agreement which would enable them to discontinue the lighting of all or any of the gas lamps at a month's notice. The present agreement was very much in favour of the Company, and, as they had many applications for the better lighting of the side streets, they wished to have the powers asked for. The report was approved.

BRISTOL.—Some time ago the electrical engineer (Mr. H. Faraday Proctor) was instructed to prepare a report on, and furnish an estimate of, the cost of lighting the Mansion House electrically. Mr. Proctor has now presented a report, in which he states that 185 lamps would be required for the efficient lighting of the entire building. An amended report is to be prepared, comprehending a smaller number of lights.

CHISWICK.—Owing to the difficulty in connection with the proposed site for the refuse destructor premises, the work of erecting the electricity generating station has been very much delayed. At the last meeting of the District Council a letter was read from the Bourne and Grant Electricity Supply Company, who are carrying out the provisions of the Chiswick Provisional Order, stating that they had expected to commence the erection of the building at the beginning of the year. There has been some delay in the matter of the agreement for the site of the proposed station.

CITY AND SOUTH LONDON RAILWAY.—In the Bill which this Company intend to introduce in the next Session of Parliament power is sought for an extension of time until August, 1898, within which to acquire the necessary lands for the extension of their electric railway to Islington; an extension of time until August 24, 1901, three years beyond the time originally granted, for the completion of the line; power to acquire additional property in the borough; and a clause empowering the Company to construct the proposed station at Lombard-street in any form that the Company think fit, instead of the "cylindrical form" in which they are bound to construct it by the Act of 1893.

CROYDON.—The Town Council have received the formal sanction of the Local Government Board to their proposed loan of £27,000 for electric lighting purposes. The period of the loan is 25 years.

DOUGLAS (ISLE OF MAN).—The work on the Douglas Southern Electric Tramways, situated on the Douglas Head Marine Drive, is now being commenced by the representatives of the General Traction Company (Limited), who executed the work in connection with the equipping of the Coventry Electric Tramways.

ELECTRICAL PLANT AT HOUGHTON MAIN COLLIERY.—The Houghton Main Colliery Company, of Barnsley have just had put down by Messrs. Crompton and Co., an electrical plant for lighting the whole of the surface, including the head offices, weigh-houses, workshops, engine houses, screens, and the pit-yard. The plant consists of six large arc lamps, four of which are 15-ampere 3,000 c.p., two 10-ampere 2,000 c.p., and 200 incandescents, with a dynamo giving an output of 240 amperes at 110 volts. The machine is driven by an engine of the ordinary horizontal type, giving about 40 H.P. The screens, which are invariably the most difficult part of a colliery plant to contend with, on account of the dampness and rough usage, are admirably equipped. One of the main features of the work is the use of concentric wiring, which is almost a new departure, it is said, in colliery work, and appears to be a system particularly adapted to mining where dampness and rough usage are to be contended with.

Digitized by Google

FOLKESTONE.—The Corporation have decided to proceed with their application to the Board of Trade for a Provisional Electric Lighting Order.

GLASGOW.—At the last meeting of the City Council the minutes of the Electric Lighting Committee recommended that Bailie Burt and Councillors Cassells, Fife, Mitchell, Paton and Stevenson be appointed as a special sub-committee to take such action as they may deem expedient, in conjunction with the special sub-committee of the Watching and Lighting Committee, to consider the question of the electric lighting of the city, and particularly as to the kind of lamps to be used for such lighting. Bailie Burt moved the adoption of the minutes, but, after a long discussion, the matter was referred back.

HACKNEY.—The members of the Vestry met in special meeting last week to consider the report of the Sanitary Committee on the proposed dust destructors, and of the Electric Lighting Committee on the scheme for the combined installations of the electric light and dust destructor, particulars of which were set out in our issue of the 13th inst., page 238. The reports were discussed separately, the dust destructor report being first taken. Mr. Sheehan opened the proceedings with a review of the steps taken by other municipal bodies in connection with the combined electric lighting and dust destruction arrangements, especially pointing to the experience of Southampton, which after ten years had just entered into a contract for an extra destructor at a cost of £60,000. The opinion of many members was to the effect that the principle of the Committee's scheme was a good one, but that further expert assistance was required before it could be considered perfect. After a lengthy debate it was finally decided to agree to the principle of the disposition of the parish refuse by cremation, but to defer the further consideration of the details to a further meeting, when it will be again discussed in conjunction with the electric lighting report which at this meeting was not reached.

HUDDERSFIELD.—At the last meeting of the Town Council applications for current were received from Longroyd Bridge and Marsh, and the electrical engineer (Mr. A. B. Mountain) was instructed to make inquiries as to the probable demand from these districts. The charge for meter rent to customers having less than 12 lights is in future to be 7s. 6d. per annum.

KINGSTON-ON-THAMES.—At the last meeting of the Town Council a letter was received from the London and South-Western Railway Company stating that their engineer would further communicate with the Council on the question of lighting the railway station electrically. A letter was also received from Major-Gen. C. E. Webber stating that he had gone into the matter of laying a main to Ham House, but he could not advise Lord Dysart to incur the outlay; he would, however, be prepared to advise his client on any proposal the Council might have to make for supplying electric current to Ham.

KINGSTOWN (IRELAND).—At their last meeting the Town Commissioners decided to proceed with their application to the Board of Trade for a Provisional Order.

KINGSWOOD (BRISTOL).—The District Council intend to oppose the application of the Great Western Electric Light and Power Company for a Provisional Electric Lighting Order for the district.

MADRAS.—The second section of the Madras electric tramways, constructed on the overhead system, was opened for traffic on December 5th. The cars are very popular, and in addition to ordinary traffic several of the native princes are, it is stated, arranging for special trips on the new cars.

MILE END (LONDON).—At their last meeting the Board of Guardians appointed Mr. B. H. Jenkinson consulting electrician in connection with their proposed scheme for lighting the workhouse premises electrically.

NEWCASTLE.—At the last meeting of the City Council a resolution was passed that a petition be presented to Parliament for leave to introduce a Bill for the extension of the tramway system, with power to work the new sections by electricity, cable, or other motive power.

PRESTON.—At the last meeting of the Town Council a proposal of the Markets and Town Hall Committee to light the town hall and public hall electrically was referred back for further consideration.

PITLOCHRY.—The report of Prof. Forbes on the feasibility of lighting this town electrically will shortly be presented to the District Council. Under the suggested scheme water power is to be utilised.

REGENT-STREET POLYTECHNIC.—On Tuesday Mrs. Quintin Hogg distributed the prizes to the successful scholars at the Polytechnic Day Schools. Many of the prizes were awarded to lads who in the workshops of the schools had shown exceptional capacity, one of the principal subjects taken being electrical engineering. The day schools were stated to have met with such success that, although room is made for 500 boys and 200 girls, applications for admittance continue much in excess of the vacancies, some of the scholars hailing from the Colonies, and even so far afield as Japan.

SALTASH.—Trouble seems to have dogged the footsteps of the Saltash authorities in connection with their lighting arrangements. The trouble began by the acceptance of a tender for electric lighting from an undischarged bankrupt, and unless more success attends the renewed application for tenders (see last week's *Electrician*) the Council will have no other course open but to renew the arrangement with the local gas company.

STOKE-ON-TRENT.—The report of the Highways Committee on the proposal of the North Staffordshire Tramways Company to introduce a system of electric traction on the local tramways was discussed by the Town Council at their last meeting. Mr. W. J. Carruthers-Wain (manager), Mr. S. P. Sellon (electrical engineer) and Mr. E. J. Hammersley (a director), representing the Company, also attended before the Council, with the object of answering any questions on the draft agreement submitted by the Company's solicitor. After considerable discussion the Company undertook to extend the present line in London-road to Hanford Bridge within three years from August 1st last. The question of purchase at the end of 22 years was also discussed, but it was finally decided that the Town Clerk should communicate with Mr. Sellon on this point. The Town Clerk also reported that at a conference of representatives of the Hanley, Burslem, Stoke, Fenton and Longton Local Authorities, held on Wednesday last, a resolution was passed that it was desirable that combined action should be taken to oppose the proposed agreement with the tramways company for the optional purchase of the electrically-equipped tramways by the Local Authorities at the end of 22 years at a 5 per cent. reduction upon the original cost for depreciation, and asking for the substitution of a clause providing for the terms of purchase to be fixed by arbitration. He had received a notice from the Company of their intention to apply for a Provisional Order empowering them to extend the tramways, and to use electricity as the motive power. The Council decided to confirm the resolution passed by the conference of Local Authorities, and the question of the proposed Provisional Order was referred to a committee for consideration and report.

SWANSEA.—It has been decided to hold a public meeting of the ratepayers of this town in connection with the proposed electric lighting and dust destructor scheme. At the last meeting of the City Council the Mayor stated that a meeting would be held after the Christmas holidays, and that, although the Council had received tenders for the erection of the necessary works in connection with the complete scheme, these would not be opened till the final vote had been taken on the purchase of the tramways, because it was intended that one scheme should stand or fall by the other.—A reporter of *The South Wales Daily Post* has been canvassing the principal tradesmen of the High-street for the purpose of ascertaining the amount of support likely to be given to the Corporation's suggested electric lighting scheme. Several of the tradesmen interviewed announced their intention of lighting their premises electrically, and of taking current from the Corporation when it is available. Altogether the scheme is viewed with considerable favour by the leading ratepayers.

THEATRE LIGHTING.—The new theatre for Leeds, which is being built under the promotion of Mr. W. Reynolds, the lessee of the Theatre Royal, is, says *Daily Tenders and Contracts*, to be furnished with a complete electric light installation and an elaborate system of sprinklers, sliding roof, &c.

TOTTENHAM.—The District Council have appointed Mr. F. H. Medhurst to make a report on the question of the adoption of a combined electric lighting and refuse destructor scheme for the district at a fee of 50 guineas.

TRADE MARKS.—By a decision recently come to by the Patent Office officials a considerable modification has been made in Section 64, Sub-section A of the Patent Act of 1888, which regulates the use of signatures as trade marks. It has been decided that signatures, even though they be the real trading name of the company, cannot be registered as trade marks, and henceforth no signatures will be allowed unless it consist of a personal name or personal names. The Patent Office have further decided that no trade mark having no other distinctive part than a personal name, which is to be found in a directory as a surname, can be registered. Judge North has recently extended this decision to any personal name found in any book (as, for instance, the trade mark of "Trilby"), on the ground that it is a personal name in a novel, though there is no proof that it has ever been an actual surname. We are indebted to Messrs. W. P. Thompson and Co., of Lord-street, Liverpool, for the above information.

TURKEY.—It would hardly have been expected that electric light and telephone engineers and contractors would be especially interested in the present financial condition of Turkey, but the

Digitized by Google

Sultan's embarrassment has naturally compelled him to seek additional funds from the most unlikely quarters. If the correspondent of the *Daily Chronicle* is to be believed, his Majesty is contemplating the granting of concessions to electric lighting and telephone companies to construct works and exchanges throughout European Turkey. The news is, we fear, too good to be true, for probably the last thing in the world that the Sultan would care to have diffused over the country is "more light."

WATFORD.—The Urban District Council intend to apply for a Provisional Order.

ANNUAL DINNER.—On Saturday evening last the employés of Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne, held their annual dinner at the Crown Hotel, under the presidency of Mr. J. T. Thompson. In response to the toast of "The Firm," Mr. E. Holmes said that most satisfactory progress had been made during the past, as was shown by the increase in the wages bill for the previous nine months of £2,200 beyond any previous year, the wages and salaries bill of the firm now reaching about £25,000 per annum. This gratifying result had been obtained by the cordial working of the managers, foremen, and workmen, which the firm very cordially acknowledged. Considerable extensions were about to be made to their works, and large as the gathering of employés was now, with similar success in the future, this number would doubtless be largely augmented at future dinners.

ANNUAL SUPPER.—The employés of the City of London Electric Lighting Company held their first annual supper at the London Tavern last week under the presidency of Mr. D. Bates. The company at supper consisted of 180 guests, which number was considerably increased at the concert which followed.

NEW COMPANIES, STATUTORY RETURNS, &c.

DIRECT ELECTRIC GENERATOR SYNDICATE (LIMITED).—This Company was registered on December 20th, with a nominal capital of £100,000, in £1 shares, to carry into effect an agreement to be made with C. P. Shrewsbury, J. Cooper, F. L. Marshall and J. L. Dobell, and to carry on the business of electricians, generators and suppliers of electricity for the purposes of light, heat and motive power, mechanical and electrical engineers, and manufacturers of and dealers in apparatus required for the generation, distribution, supply, accumulation and employment of electricity. The first subscribers, with one share each, are: A. J. Seton, H. Dobbin, S. Spill, J. Cooper, F. L. Marshall, J. Lindsay, and E. Hills. The first Directors are: Major A. J. Seton, C. P. Shrewsbury, H. Dobbin, J. Cooper, and F. L. Marshall.

FORT WILLIAM ELECTRIC LIGHTING COMPANY (LIMITED).—This Company has been registered at Edinburgh, with a capital of £7,000 in £5 shares, to carry on business as electricians and electrical engineers, suppliers of electric current for light, heat and motive power purposes in the Burgh of Fort William. The subscribers, with one share each, are: A. S. M'Intyre, J. M'Donald, N. B. Mackenzie, D. Macniven, D. M'Leish, D. Cameron (all of Fort William), and R. F. York, electrical engineer, of Glasgow.

J. C. HOWELL & COMPANY (LIMITED).—This Company was registered on December 20th, with a capital of £10,000 in shares of £1 each, to acquire all or part of the business, goodwill, machinery, rights, privileges and other property which formerly belonged to John C. Howell, electric light engineer, New Dock, Llanelly, Carmarthen, and 24, Queen Victoria-street, London, E.C., and which recently belonged to J. C. Howell, (Limited), to acquire any letters patent, rights or monopolies relating to inventions for the production or supply of light, heat or power by means of electricity, magnetism, or other agent; to manufacture, sell and let electrical apparatus, and to contract for the lighting of any public or private place by electricity. The first subscribers, with one share, are: A. G. Hudson, S. Jordon, W. Escott, A. W. N. Stuart, T. F. Goddard, W. F. Smart and C. T. Lissenden. Mr. J. C. Howell is to act as the sole Managing Director at a remuneration of £800 per annum.

SALT CHEMICALS SYNDICATE (LIMITED).—This Company was registered on December 19th with a capital of £5,000, in shares of £5 each, to acquire patents, brevets d'invention, or licences relating to an invention for the production of caustic soda by electrolysis.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 30 7/16d. per oz. (Dec. 24th). Consols (2¾ per cent.) 106 9/16—106 11/16 for money, 106⅞—106¾ for account; 2½ per cent. 103—103½ (Dec. 24th). Stock Exchange Settling Days: Consols, Jan. 3rd; Stocks and Shares Continuation Day, Dec. 27th; Ticket Day, Dec. 28th; Pay Day, Dec. 30th.

ANGLO-PORTUGUESE TELEPHONE COMPANY, (LIMITED).—Coupons No. 16 of the First Mortgage and No. 11 of the Second Mortgage Debentures of this Company will be paid (less income tax) by Parr's Banking Company at the Alliance Bank on and after January 1st.

ARMSTRONG (SIR WILLIAM G.), MITCHELL AND CO. (LIMITED).—The directors of this Company have just issued a circular to the shareholders stating that a careful valuation of the Company's property reveals the fact that the assets are greatly in excess of the figure at which they stand in the books. It has therefore been decided to increase the nominal capital of the Company, from £2,000,000 to £3,000,000. This to be alloted as fully paid to the holders of the existing ordinary stock in proportion to their present holdings. The Preference shareholders will have the option of being paid off at a premium of 10 per cent., or of taking fresh Preference shares bearing interest at the same rate. In order to give effect to these proposals a reconstruction of the Company is necessary, and a meeting of shareholders will be held on Tuesday next for the purpose of passing the necessary reconstruction resolutions. It is also stated that some of the workmen will get a bonus as a result of the reconstruction, a portion of their funds being invested in the 5 per cent. Preference stock of the Company. This Company, in addition to occupying a proud position in the shipbuilding world, are the manufacturers (for the British Thomson-Houston, Limited) of Thomson-Houston plant and apparatus in this country.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended December 22nd were £1,013, against £968 in the corresponding week of 1894, an increase of £45. The total receipts for the half-year amounted to £22,553, against £22,447 in the corresponding period of 1894, an increase of £106.

ELMORE'S AMERICAN AND CANADIAN PATENT COPPER DEPOSITING COMPANY (LIMITED).—The meeting of shareholders in this Company takes place at Leeds on the 30th inst. at 2 p.m. The Directors' report states that the improvement in the Company's finances shown in the accounts of the previous year has practically been maintained, as, after meeting the total administration expenses for the year, amounting to £165, compared with £230 last year, the Board have been able to reduce last year's debit balance from £877 to £452, making a reduction of £1,626 in two years. The unpaid balance of the loans to the French Elmore Company now stands in the books at £6,831, for which this Company holds 218,513·38 francs (equivalent to £3,740 at 25 francs to the £ sterling) of 6 per cent. First Obligations (Debentures) of the Société Francaise d'Electro Metallurgie, upon which the Company has regularly received interest half-yearly since January 1, 1894; and two of the Obligations have been redeemed at par by the Société, who annually redeem at par a certain number of the Bonds drawn by lot. The Directors regret they cannot report the sale of the Company's rights in America and Canada, as they felt that the time was not yet ripe to actively push such sale until further developments have been made in this country and in France.

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED).—The Directors' report for the year ended June 30th last, to be presented to the annual meeting to be held at Leeds on the 31st inst., at two o'clock, states that for the first half of the year the works were principally employed in completing the plant, and accordingly the greater part of the expenses, amounting to £2,720. 11s. 5d., has been charged to the old administration account, and the result of the working for the second half is a loss of £356, which cannot be considered unsatisfactory in view of the small turnover. The Directors have decided to appropriate the amounts received on forfeited shares and on share premiums (£64,282. 10s.) to the reduction in valuation of licences (£31,940) and to the writing off of administration account (£26,280. 19s. 1d.), leaving a balance as reserve for future contingencies of £6,061. 10s. 11d., out of which they now propose to provide for the £356 standing to the debit of profit and loss account, and thus enable the Company to start on the current year unencumbered by any old losses. The capital expenditure on buildings, plant, machinery, &c., amounts to £5,791. 17s. 5d., a considerable part of the outlay being for a rolling mill for the production of special sheets. Sales and deliveries to customers have steadily improved during the second half of the year. The Directors state that the Company's manufactures have given every satisfaction, and that numerous offers of orders for high-class specialities have been received, but cannot be accepted until the Company is in a position to put down the special plant and tools required. The increasing difficulties of obtaining the most suitable raw material with the present limited working capital of the Company has induced the Directors to so work the factory as to prove the practical value of the process on a commercial scale, the ultimate object being to secure capital not only to purchase raw material direct from the mines, but to provide the special plant necessary for still further developments. The Director retiring from the Board by rotation does not offer himself for re-election.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 22nd inst. amounted to £1,080. The amount for the corresponding week last year was £938, an increase of £142.

NATIONAL TELEPHONE COMPANY (LIMITED).—The transfer books of the 3½ per cent. Debenture Stock of this Company will be closed from the 23rd to the 31st instant, inclusive, for the purpose of preparing the warrants for the half-year's interest due January 1st.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY.—The coupons on this Company's 6 per cent. First Mortgage Gold Bonds due January 1st next, will be paid at the National Provincial Bank of England, 112, Bishopsgate-street, E.C., or at the Farmers' Loan and Trust Company of New York.

WEST COAST OF AMERICA TELEGRAPH COMPANY, (LIMITED).—The coupons on the Debentures of this Company, due the 31st instant, will be paid by Messrs. Barclay, Bevan & Co., Lombard-street, E.C. Coupons should be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended December 20th, 1895, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,677.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 920. [Vol. XXXVI. No. 10.] FRIDAY, JANUARY 3, 1896. PRICE SIXPENCE.

NOTES.

THE collection, compilation and co-ordination of data relating to English central station enterprise which has been undertaken annually by this journal since 1889 is becoming—thanks to the steady growth of the industry every year a more onerous task; indeed, were it not for the ready assistance of central station engineers all over the country, it would be impossible to present a table to our readers bearing any close relation to the facts of the case. We do not ask questions and glean statistics in a spirit of mere idle curiosity, but in the hope that by making accurate data available to the world at large, and to electrical engineers in particular, erroneous notions may be dissipated and progress accelerated. The scientific habit which characterises the electrical industry above all others is exhibited in nothing more strikingly than in the penchant for a systematised knowledge of what is being done around them displayed by members of the electrical profession. Notwithstanding our endeavours to avoid pointless interrogatories, a few of the forms sent out have been filed in the waste paper basket; no doubt inadvertently. The half-dozen exceptions to the general rule of careful revision and prompt return of our printed slips render our thanks to the majority all the more cordial.

OF the hundred patents which figure in our list of electrical patents expiring this year more than 10 per cent. originated in the fertile brain of Mr. EDISON, and, as the papers informed us quite recently, he is as full of resource as ever, and doubtless before long the English Patent Office will be honoured with a "communication from abroad" of a method for destroying the British fleet by means of that 5,000-volt jet, upon which Lord ARMSTRONG has thrown some much-needed cold water. Glow lamp patents figured very prominently in 1882, as is witnessed by the names of CROOKES, RAWSON, WERDERMANN, MAXIM, AKESTER, LANE-FOX, CRUTO, SWAN and BERNSTEIN. Arc lamps also were much be-patented fourteen years ago, patents having been taken out by JARMAN, SOLIGNAC, WESTON, LEVER, KRIZIK and PIETTE. Among other patents with historic names attached to them we may note the one taken out by Lord ELPHINSTONE and Mr. C. W. VINCENT, the telpherage patents of Prof. FLEEMING JENKIN, the telegraphic-telephonic patent of VAN RYSSELBERGHE, and, finally, Patent No. 3,204 of ELIHU THOMSON. In July Dr. JOHN HOPKINSON'S famous three-wire patent will come to an end, and with it the royalties now being paid to its lucky owners by the majority of low-pressure systems in this country. On September 18th the Gaulard-Gibbs patent for distributing electricity by secondary generators would have expired had it not been revoked in July, 1888, by Mr. Justice KEKEWICH at the instance of Mr. FERRANTI. On the whole, the electrical industry will not be fundamentally affected by the removal of patent restrictions during 1896.

THIS week the Gülcher dynamo patent, No. 64 of 1882, terminates. In this there is the following curiously-worded passage:—"This form (U-shaped pole-pieces and V-shaped armature core) not only permits of a convenient and solid fixing of the inductor, but also allows the wires wound round it to be exposed to the inducing action of the magnetic pole-surfaces from all sides, and thereby completely obviates the production of heat, which in other machines is produced by the passage of the electric current through those parts of the wires which are not exposed to the said action."

BURKE, we believe, declared himself unable to draw up an indictment against a whole nation. A special committee of representatives of German Electric Supply Companies, however, has not flinched from drawing up an indictment of an entire industry. In another column will be found a lengthy document setting forth without circumlocution the parlous state into which the German glow lamp industry has fallen by reason of unscrupulous competition. For some years there has been an ever-increasing chorus of guttural complaint, and finally, with a view to protect the electric light supply business, a special committee was appointed to inquire into the whole matter. The investigation appears to have been carried out with characteristic German thoroughness, and the native glow lamp has been condemned *sans phrases*. Not only are the lamps of indifferent manufacture, negligently tested, and carelessly sorted, but something like wilful fraud is not uncommon. Such, indeed, has been the doleful experience of the committee, that they pronounce the 3½-watt lamp and the guaranteed life of 1,000 hours or thereabouts as figments of the makers' imagination, and they suggest that 4 or 5 watts per candle and a "useful life" of 400 hours would be more in accordance with the actual facts. So well grounded do the committee deem the complaints of consumers to be, that they are led to recommend the drastic measure of electric light concerns taking the supply of glow lamps into their own hands, supplying the lamps to their consumers for nothing.

Digitized by Google

We do not know how this last idea will commend itself to electric light undertakers in this country; but if the advent of the cheap glow lamp leads to the same results in England that it has in Germany, they will, whether they like the idea or not, have to do something of the kind. The gratuitous supply of lamps to customers is a serious step, not to be taken except in the last resort; but electric light concerns might, in self-defence, very well take upon themselves to supply carefully-tested lamps at cost price to all consumers who may desire them.

When Prof. J. J. Thomson first announced his discovery that the ions of a gas undergoing electrolysis may become either positively or negatively electrified, quite irrespective of their normal condition of electrification, we ventured to suggest that a new field of electrostatic discovery was opened up. Hardly, however, could anyone have guessed the wealth of new phenomena which lay behind Prof. Thomson's ingenious researches, first on the electrolysis of steam, and subsequently on that of other compound gases. Yet it was not altogether hidden from view that the trend of these researches would probably lead to an important elucidation of "The Relation between the Atom and the Charge of Electricity Carried by It," which is the title of Prof. Thomson's latest publication on this line of research. We commence this week a reprint of this Paper, which embodies practically the whole of the material developed in the Paper itself. This valuable contribution to science forges one more link in the chain which connects inseparably chemical and atomic phenomena with the electrical condition and properties of atoms. And the link, like the chain itself, is all the more real from the fact that it is so directly based upon experimental evidence and so free from metaphysical cobweb-spinning.

The early part of Prof. Thomson's Paper seeks to establish the proposition that when charged atoms are close together there may be forces, partly electrical, partly chemical in their origin, in addition to those expressed by the ordinary laws of electrostatics. In fact, as subsequent parts of the Paper show, the individual relationship between pairs of atoms close together is very different from the ordinary electrostatic behaviour of atoms in the bulk; and the key to much of the anomalous in the behaviour of electrolysed gases appears to lie in the properties of thus isolated small groups or pairs of atoms. The forces between charged atoms placed very near together seem to be modified by the electro-chemical properties of the atoms; in consequence of which, as Prof. Thomson states, an electro-negative atom, if positively charged, cannot, in the absence of a strong external field of electric force, interchange its charge with the negative charge on an electro-positive atom, unless the two are connected by an external conducting circuit. The application of this theorem, by way of illustration, to the case of the oxidation of zinc, is full of interest, and particularly where the conditions which limit the extent of the chemical combination are discussed. Interesting, too, is the investigation of the minimum potential difference between electrodes which is requisite to produce a spark in a gaseous electrolyte. Prof. Thomson shows that it is highly probable that this minimum potential difference is of the same order as the potential difference between the atoms in a single molecule, when that molecule is so placed that there are no surrounding molecules to influence its electrostatic condition. Possibly the two are even identical, allowance being made for the influence between the molecules which will always be present when a volume of gas is being traversed by an electric spark.

Glasgow and West of Scotland Technical College.—The second term of this College opens on January 7th.

Cable Interruptions :—

	Date of Interruptions.
Puerto Plata-Martinique	December 19.
Aden-Zanzibar	December 24.

Transformer Patent Litigation in Italy.—The action Zipernowsky, Déri and Bláthy *v.* Siemens and Halske, relating to transformer patents, will be discussed before the Corte d'Appello of Florence next week.

Electrical Standardising, Testing and Training Institution.—Mr. James Swinburne will commence his usual course of lectures on "Dynamo and Transformer Construction" at the above Institution on Thursday, January 9th.

Appointment Vacant.—A Junior Demonstrator in Physics is wanted by the authorities of University College, Nottingham. Commencing salary £120 per annum. Applications must be sent in to the Secretary by January 9th on a special form.

New Year Honours.—Amongst the recipients of New Year honours is Mr. Henry Charles Fischer, Controller of the Central Telegraph Department of the General Post Office, upon whom the Cross of St. Michael and St. George has been conferred.

Fareham.—The ratepayers of Fareham, or the portion of them who voted—not one-half of those on the list took the trouble to go to the poll—have decided by 431 to 235 to purchase the local electric light company's undertaking.

Institution of Civil Engineers.—The new edition of the list of members of the Institution of Civil Engineers—dated January 2, 1896—shows that this Corporation has now on its roll 6,794 members of all classes, representing an increase during the last ten years of 36½ per cent.

Electrical Engineering Courses at the Oxford Technical School.—Mr. J. Hardie McLean, M.I.E.E., manager and engineer of the Oxford Electric Company, has been appointed lecturer and demonstrator of Electrical Engineering and Electric Lighting at the City Technical Schools, Oxford. A course of 20 lectures will be given during the session.

Aden-Zanzibar Cable.—This cable was unfortunately interrupted on December 24th, and no notification of its repair had come to hand up to the time of going to press. The repairing ship was expected on the ground yesterday (Thursday). Messages from the Transvaal are being dealt with as promptly as possible by the Western route. Owing to the heavy Government traffic over the lines at the present time some delay is caused to private messages. But for the serious news from the South African Republic, little inconvenience would have been caused to the public.

The South Staffordshire Tramways.—As a result of the efforts of the Streets Committee of the Walsall Town Council, arrangements have been come to between the South Staffordshire Tramway Company and the Electrical Construction Company by which the electric cars will be continued until January 31st. This is with a view to a permanent arrangement being made, and the Mayor (Councillor Noake), who acted as mediator between the two companies last year, has consented to meet their representatives again in order to assist them in arriving at a settlement.

Electric Traction for Teheran.—A Reuter's agent at Teheran, writing under date November 18th, says: "A concession for the construction of a road which is to join Baghdad with Teheran has just been granted to Mr. Felix Moral, the representative of a number of important German houses. It is expected that

Digitized by Google

the road will become the principal trade route between Persia and the West. The concession is for 75 years from the date of signature (November 7, 1895), and concedes the right of constructing the road, levying tolls on it, and working a transport service. The work must be completed in two years and a-half. Mr. Felix Moral also obtained a concession for the construction and working of a steam or electric tram from Teheran to the villages north of the city, a distance of about ten miles. This concession is for 90 years."

The Requirements of Deaf Telephone Subscribers.—Judgment was given at Glasgow on Friday last in an action raised by the National Telephone Company against Mr. H. Wilkie, watch and chronometer maker, Duke-street, Glasgow, for payment of £7s. 15s., the rent of a private telephone wire, and a further sum of £10, the rent of an exchange wire. Defender was somewhat hard of hearing; but this was explained to the Company's canvasser, and it transpired the latter quite understood that the instrument was to be used by defendant personally. The Court held that it was an implied condition of the contract that the wire and instrument should be fit and serviceable for defendant's special case, and that the Company had failed to make it so in spite of repeated complaints by him. It therefore gave a verdict for the defendant and granted him expenses.

Test Box Explosion.—"Late on Monday night." says a morning paper, "residents of Crucifix-lane, Long-lane, Bermondsey, were startled by a very loud report. Immediately a deep hole was discovered in the street beneath the railway arch, and some kerb and pavement box-covers, the property of the London Electric Supply Corporation, were damaged. Mr. Targett engineer of the outdoor department of this Company, inspected the place. Captain Simonds attributes the explosion to 'the failure of the insulation of the main.'" We are informed by Mr. d'Alton that this account is greatly exaggerated. The cause of the explosion was the failure of one of the Company's test boxes on the trunk mains. There were no pavement or kerb stones disturbed in any way by the explosion. The Company's men had been working at the spot the same day, making some alteration in the boxes.

High-Voltage Glow Lamps.—The following letter appeared in the *Builder* of December 28th:—

SIR: I have read with interest your notes on the Edinburgh Electric Lighting Works, especially those relating to the introduction of high-voltage lamps. The gain to the supplying agents is manifest. The gain to the consumer is, to say the least, doubtful, and where corporations or vestries undertake the work, I think the latter deserve some consideration. This house is supplied by the St. Pancras Vestry; but though the mains were laid several months before I adopted the light, no notice was sent of any intended change in the conditions of supply, and the house was partly wired as for 110-volt lamps, when I found out the change. Unlike Edinburgh, there was no option in the matter, or most certainly I should not have agreed to use the higher pressure. The candle-power does deteriorate more rapidly (unless, that is, the Vestry do not maintain the proper voltage in their mains), and I have had to change some after about 500 hours' use. There are other drawbacks to their use besides the higher charge (English lamps are 2s. each). There are no 5 c.p. lamps to be had; there are no obscured lamps yet made. The lamps are larger than the 110 and 100-volt lamps, and will not go in many shades. The meters are not specially made for the higher voltage, though this may be, after all, no real objection.—"ST. PANCRAS." P.S.—I enclose card.

A Polyphase Transmission Plant for Guatemala.—Messrs. Siemens and Halske, of Berlin, have in course of construction a long-distance transmission plant which is to be operated by the "Empresa Eléctrica de Guatemala," and which is intended to carry electric energy for light and power purposes to the town of Guatemala from a waterfall 22½ miles distant. The system of transmission is the three-phase, at a pressure of 10,000 volts, with step-up and step-down transformers at either end of the line. Power is to be derived from the outlet of a lake giving 2,000 litres per second, with a fall of 87 metres. At present, therefore, some 1,300 H.P. is available. But it is contemplated in the near future to carry out works permitting the water of the lake to be accumulated during the daytime; this will bring the available power to 5,000 or 6,000 H.P. The plant now in view consists of a set of two horizontal Nagel and Raemp turbines of 520 effective horse-power each, running at 200 revolutions per minute. Each turbine is coupled direct to a Siemens and Halske three-phase alternator capable of generating 425 kilowatts at a pressure of 350 volts. The current is transformed by a set of four transformers from the pressure of 350 to 10,000 volts, then transmitted to the town by a three-conductor aerial line having an aggregate section of 105 sq. mm., the maximum loss in the line amounting to 10 per cent. On reaching the town the pressure is lowered again by another set of four transformers from 9,000 to 1,000 volts, the current being then distributed to the supply network of the town. The distributing conductors are overhead, carried on iron poles.

Alternate-Current Transformers.—The following is the syllabus of the course of Cantor Lectures on "Alternate-Current Transformers," which are to be delivered at the end of this month by Dr. J. A. Fleming:—

January 20th.—Lecture I.—"The Action of the Transformer."—Real and imaginary transformers—Transformer diagrams—Alternate-current curve tracing—Various forms of curve tracers—Discussion of transformer diagrams—The harmonic analysis of diagrams—The curves of induction and hysteresis—Magnetic leakage—Core and copper losses—Effect of variation of form of the electromotive force curve on Core losses—Variation of core losses with temperature—The power factor. *January 27.*—Lecture II.—"The Construction of the Transformer."—The core—Sheet iron stampings—Building the core—Prevention of core losses—Selection of iron—The coils—Coil winding—Insulation of coils and core—The case—Ventilation and surface radiation—The terminals—Primary and secondary fuses and switches—Sizes and forms of transformers in practice—Open and closed circuit transformers. *February 3rd.*—Lecture III.—"The Testing of Transformers."—The measurement of the power taken up in an inductive circuit—The theory of the wattmeter—The construction and use of the alternate-current wattmeter—Various methods of measuring alternating-current power—The testing of transformers—Testing by curve tracing—Testing by the wattmeter—Differential testing—Practical tests in the sub-station and workshop efficiency curves—Core losses for various sized transformers—Specifications for transformers—Measurement of copper losses and drop—Iron testing. *February 10th.*—Lecture IV.—"The Employment of the Transformer."—Defects in transformers—Causes of failures—Current rushes into transformers—Variation of core losses, with time and temperature—House transformers—Sub-station transformers—Two and three-phase transformers—Transformer distribution—Importance of large power factor—Influence of load factor on annual losses—Capacity—Effects in case of large transformer systems—Designs for alternating-current stations—Conclusion.

The Annual Awards of the Académie des Sciences.—The last number of the *Comptes Rendus* is taken up with announcements of the 1895 prizes awarded for scientific, mathematical, and engineering work. We append a list of the prizes awarded for electrical researches:—The MONTYON PRIZE of 700fr. has been awarded to M. Galliot for his successful introduction of an electrical towing arrangement for a distance of 6 kilometres on the Burgundy Canal. Some two years ago M. Galliot decided to electrically utilise the head obtainable between the feed-water reservoir and the third lock on either side of it, and since then all barges have been towed up and down by a motor-barge deriving its current from a trolley wire running along the banks of the canal, and connected to turbine-driven dynamos. The water necessary for the operation of the locks is not interfered with, the turbines being fed by the large volume of water necessary to make good the losses by infiltration.—The LA CAZE PRIZE of 10,000fr. was awarded to M. Edmond Bouty, Professor at the Paris Faculty of Sciences. M. Bouty discovered a curious phenomenon connected with electro-plating, to which he gave the name of "electrostriction." For instance, if a thermometer bulb be copper-plated an appreciable permanent displacement of zero is found to take place, corresponding to a pressure of several atmospheres. M. Bouty's explanation is, that this phenomenon of expansion or contraction is due solely to abnormal temperature, caused by the Peltier effect. Recently M. Bouty has investigated the influence of the layer of air left between the metal plates of a condenser and the solid dielectric, and, finding it considerable, M. Bouty now silvers the faces of his mica condenser sheets.—Another LA CAZE PRIZE was awarded to M. H. Le Chatelier, well known for his work on the electric pyrometer. By the aid of this instrument he has, amongst other things, observed that at 580°C. quartz suddenly expands, though its molecular composition is not modified; the process is reversible.—As we have already announced, the LECONTE PRIZE of 50,000fr. was awarded to Lord Rayleigh and Prof. Ramsay for their discovery of argon.—The GASTON PLANTÉ PRIZE, a biennial one of 3,000fr., was awarded to MM. J. and P. Currie for their work in "piezoelectricity."—The KASTNER-BOURSAULT PRIZE of 2,000fr. was awarded to M. Baudot, the inventor of the well-known multiple-writing telegraph so much affected in France.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 215*).

The Gas Engine in Relation to Electric Power.

The following *schema* indicates the uses which have hitherto been made of the gas engine for electrical power purposes:—

I. Private electric light and power plants.

II. Public electric supply
- (1) As auxiliary motors in steam stations.
- (2) In secondary stations feeding mains chiefly supplied by power from steam stations.
- (3) In gas engine electric supply stations.

III. Electric traction generating stations.

Private Plants.—The use of the gas engine for driving private electric light plants is almost as old as the dynamo itself. In combination with a capacious storage battery, the gas-driven dynamo is admirably adapted to the majority of cases. The chief merits of a gas engine thus used are: (1) convenience of starting and stopping; (2) small attendance required during running; (3) low initial cost of plant; (4) small risk of explosion or fire; and (5) low cost of fuel where town gas is cheap or where Dowson gas can be used.

Auxiliary Motors.—Many electric supply stations are provided with gas engines covering a small percentage of the total capacity of the station, the purpose of these being to relieve the steam plant of the very low loads which occur during the daytime, and to supply the extra power which may be required for a very brief time during a sudden rise in the demand for power. It has been found that this practice very considerably improves the load factors of the engines and boilers; and, owing to the ease with which gas plant may be started and stopped and the absence of loss during idle hours, the practice has been recommended by the highest authorities.

Secondary Stations.—An example of a gas engine secondary station is to be found at Brussels, where the network of electric supply mains is chiefly fed from a large steam driven station, but where, recently, a gas engine station has been erected to supplement the supply. This secondary station is situated at some distance from the main station. It will ultimately consist of five 120 H.P. sets. Each set, of which two are now erected, will consist of a twin cylinder horizontal gas engine, working on the Otto cycle, direct coupled to two ten-pole dynamos; and the speed of the set is 150 revolutions per minute. The two dynamos are coupled through Raffard clutches to the two ends of the crank shaft. There is a storage battery of 500 Board of Trade units capacity. The gas engines have proved to an economy of 23·1 cubic ft. of gas per brake horse-power per hour at full load, and 33·25 cubic ft. per brake horse-power per hour at half load. It should be mentioned that although the normal load is 120 H.P., each set has been built to stand a maximum of 135 H.P.

Main Stations.—Up to the present time there have been but three public electric supply stations wholly dependent upon gas power, in the United Kingdom. These are the Morecambe, the Coatbridge and the Belfast stations. At Leicester, the Midland Railway Company have a gas-engine station for supplying the light in their railway station and goods yards. Various systems are represented by these four stations, as will be seen by the summary given in Table XXXI.

Similar stations have been long in existence on the Continent and in the United States. The first to be erected was that at Dessau, in Germany, in September, 1886. This station was established by the Imperial Continental Gas Association, in the belief that it would not only promote the use of their gas in the daytime, but also cheapen the production of light. The great success of this station led to the rapid introduction of others. Direct-coupled gas engines and dynamos are a feature of these Continental stations; but until recently this type of engine has been absent from the United Kingdom. A direct-coupled set is, however, about to be placed in the Belfast station.

Table XXXI.—*Gas-Engine Electric Supply Stations in the United Kingdom.*

Place.	Capacity of station.	Gas supply.	Equipment.
Morecambe...	3,000 lamps (wired). 5,200 lamps (possible).	Dowson gas.	1 Dowson gas plant of 150 H.P. 2 Ditto of 75 H.P. each. 1 Storage tank of 1,500 cubic ft. capacity. 2 Small vertical boilers. 1 "Crossley" gas engine of 100 H.P. 3 "Stockport" gas engines of 25 H.P. Storage cells.
Coatbridge ...	3,756 lamps (wired). Output= 11,623 units in winter quarter.	Gas of same composition as Dowson gas.	2 Dick, Kerr and Co.'s gas generators of 120 H.P. each. 1 Gas holder, 15ft. diameter, 10ft. deep. 3 Dick, Kerr and Co.'s side-by-side gas engines of 120 H.P. each (rope coupled to alternators).
Belfast.....	8,500 lamps (wired). 6,100 to be maximum of actual load.	Town gas.	4 "Kilmarnock" tandem gas engines of 120 H.P. each. 2 Ditto of 55 H.P. each. 2 Storage batteries, each of 63 E.P.S. cells of 34-K type.
Leicester, M.R. Station.	1,200 B.T. units per diem. of 24 hours.	Dowson gas and occasionally town gas.	2 Dowson gas plants of 100 H.P. each when using coke. 1 Gas holder. 4 "Crossley" gas engines of 50 H.P. each. 2 "Crossley" gas engines of 27 H.P. each.

Electric Traction.—The use of the gas engine in electric traction work has been limited to a few small instances. The only example in this country is the light railway along Brighton beach, which derives power from a single 12 H.P. "Crossley" gas engine. Accurate figures of results are difficult to obtain, but it would seem that the gas engine is well adapted to this class of work. This type of electric traction station is, however, more commonly met with on the Continent than in this country. At Zurich there is an electric line 2¼ miles long, on which 14 motor cars are run, the current for which is derived from two dynamos driven by an equal number of gas engines, aggregating 240 H.P. At Lausanne an electric railway is operated from a power house, in which the dynamos are driven by two 180 H.P. "Crossley" gas engines. Producer gas, generated from anthracite is used, the best consumption being 1·2lb. of fuel per horse-power per hour. The engines are run from 18 to 20 hours per day, and an average consumption of 4·5lb. of anthracite per car-mile is attained.

Initial Costs.—The initial cost of a Dowson gas plant varies from £138, for a plant capable of generating 900 cubic ft. per hour, and suitable for 8½ B.H.P., to £273, for a plant capable of generating 7,000 cubic ft. per hour, and capable of driving 80 B.H.P. These prices include the generator, cooler, scrubbers, holder, &c., complete. The cost of erection will vary with local conditions; but it may be taken as averaging £15 for the smaller size mentioned, and from £20 to £30 for the larger size.

The cost of a gas engine depends largely upon the type and maker selected. A 10 H.P. engine will average about £140, complete with water tank and pipes; an engine of 100 H.P. will probably cost between £500 and £550 complete, including cost of erection. These costs are for engines using town gas of good quality. Where diluted gas has to be used the engine will have to be somewhat larger for the same amount of power, and will therefore cost more.

Gas Engine Testing.

Before adopting any particular gas engine for electrical work it should be subjected to a number of short tests or trials. Some of these will be of a general character; others

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

will be based upon the special claims advanced by the makers, or upon the nature of the work to which the engine is to be put. In the matter of general testing, it would be difficult to find a better model upon which to base operations than the Society of Arts' Trials of Motors for Electric Lighting, 1888-9; and a brief account of these will be given in the present section.

Society of Arts' Trials.—During these trials, which were undertaken by Profs. J. Hopkinson and A. B. W. Kennedy and Mr. Beauchamp Tower, in September, 1888, three gas engines, besides one steam engine, were tested. We will confine our attention to the gas-engine trials. The following is an abstract of the introductory portion of the Report*:—

"The trials were carried out in a building specially erected for the purpose, on a portion of the site of the Imperial Institute at South Kensington. The tests comprised an efficiency test during a six hours' run for each engine at full power, a three-hours run at half power, and a test running light. In addition to these, one or two tests were made at the request of the exhibitors themselves, under conditions varied from the conditions of competition. In the case of the gas-engine tests, the quantity of gas consumed in the engine itself and in the ignition was separately measured, the readings of the meters being taken every quarter of an hour. The meters were Wright's standard wet meters, one of 100 and the other of 20-light size. The pressure and temperature of the gas were measured in the meter, and in each case samples of the gas were taken from time to time, were mixed together for each test, and were analysed by Mr. C. J. Wilson, F.I.C. The results of these analyses will be found in Appendix I., at the end of this report. Indicator diagrams were taken at intervals of a quarter of an hour, the diagrams being taken approximately midway between the times at which the gas was read. The indicator used for the Crossley engine was an improved Richards, made by Elliott and Co., and the same indicator and spring, with another similar one, was used for the Griffin engine. For the Atkinson engine a strengthened Crosby indicator was used. In all cases the indicator springs used have subsequently been tested. The errors being exceedingly small, a correction is not applied in calculating the results given later in respect to each engine. The brake horse-power was in all cases ascertained by means of a rope brake upon the flywheel or flywheels of the engine. Two ropes were used for each wheel; they were kept at the proper distances apart and in fixed position upon the flywheel by means of transverse wooden distance pieces. The dead load was applied by means of weights, and the back tension necessary to put the friction on the brake, by means of a spring balance. The spring balance was read every five minutes, and its tension was deducted from the dead load applied. This brake was found to work perfectly satisfactorily, and its results are certainly beyond suspicion. It is important, however, if any metal be used for attaching the wooden cross pieces to the ropes, it shall not rub against the rim of the flywheel; if this should occur, the metal becomes exceedingly hot, and is liable to burn the rope. The quantity of water used for cooling the cylinder of the engine during the run was measured by means of a Schonheyder water meter, and its temperature on emergence from the engine was ascertained by a thermometer. The meter was tested after the trials and found to be without sensible error. The number of revolutions made by the engine was measured by means of a counter continuously geared on to the crank shaft of the engine. This counter was read every quarter of an hour, at the exact instant at which the gas-meter was read.

In addition to the efficiency tests of the engines, tests were made to ascertain the regularity of running and of governing. For this purpose the engines were employed to drive a dynamo machine, and the current from this machine was taken through a metallic resistance controlled by switches; an incandescent lamp was also connected to the machine. The amount of cyclic variation occurring in the driving was ascertained by direct observance of the lamp. For electric light motors this is of course a sufficient test, as an engine running so regularly that the variation can not be detected in a lamp may be taken as being perfectly satisfactory for the production of the electric light. The resistances gave a great facility for speedily varying the load upon the engine. The speed of the engine was ascertained when fully loaded, and when running with the dynamo machine upon open circuit: it was also ascertained when running at half power. Observations were made of the effect of throwing off the load as the engine was running, and the hunting of the governor was judged by the pulsations, if any, which ensued in the incandescent lamp.

Appended to the account of the experiments on each engine will be found what may be appropriately described as a heat table. In the case of the gas engines this gives the heat of combustion of the gas, the quantity of this heat accounted for by the indicator diagrams, and the heat carried off by the cooling water. This leaves a balance which will be mainly accounted for by the loss due to the heated exhaust gas, together with a small amount due to loss by radiation and convection from the surfaces of the engine. If the quantity of gas and its temperature of exhaust were known, the former and larger of these amounts would be calculable. A very excellent approximation can be made to the quantity of waste gas from the known volume of the cylinder, the only doubtful point being the temperature of the charge when the cylinder is just filled. It is not likely that this temperature will exceed the temperature of the cooling water. Taking this to be the true temperature of the charge immediately before compression begins, the temperature is calculable at which this gas must enter the exhaust to account for the balance.

* This valuable Report is published in pamphlet form by the Society of Arts.

"As the temperatures in the gas engines can be estimated by the method just mentioned, the trials enable us to say what proportion of the heat received would have been turned into work by an engine working as a "perfect" engine between those temperatures, and therefore, to find the actual efficiency of the engine as compared with this standard."

A Typical Trial.—The course of testing indicated in the foregoing was followed in the case of all three engines, but we will here notice only one instance—viz., the trials of the Atkinson "Cycle" engine:—

"Five experiments, in all, were made with this engine, and they will be distinguished by the letters A, B, C, D, and E. Trial A was a full-power trial of six hours' duration, and trial B a half-power trial of three hours. In trial C the engine ran without load for half an hour. Trials D and E were special short trials with full brake load, but at speeds below the normal."

The principal results of these five trials are summarised in Table XXXIV. The maker elected to run the engine at 9½ B.H.P. normal load, and at 130 revolutions per minute normal speed. A rope brake was placed on each of the two pulleys, the ropes being worked perfectly dry—without lubricant or cooling water. It should be mentioned that care was taken to keep the loads of the two brakes as nearly equalised as possible.

Table XXXIV.—*Atkinson Gas Engine Trials.*

Date (1888)	Sept. 21	Sept. 22	Sept. 22	Sept. 24	Sept. 24

Corresponding indicated horse-power	0·26	—	—	—	—

Steadiness in Running.—An important matter affecting the suitability of a gas engine for electrical work is the amount of variation in speed of the engine which takes place during one cycle, when the load is constant. The variation is presumably greater than in a steam engine, owing to the lesser frequency of the impulses in the gas engine. Several methods have been proposed for determining the amount of this variation, and some of these have been actually used. The judges in the Society of Art's trials, just referred to, have appended to their Report a recommendation of the instrument shown in Fig. 81, though this instrument was not actually adopted for any of the results given in the Report. The judges give the following description of its construction and use:—

"This instrument was designed by Mr. H. B. Ransom in the engineering laboratory at University College. It consists of a drum covered by a prepared and blackened (smoked) paper, which drum revolves with the shaft whose velocity is to be measured. Near to the drum a tuning-fork is kept in vibration by means of an electric current. This tuning-fork is carried on a slide rest, and actuated by a screw in such wise as to travel parallel

Digitized by Google

to the axis of the drum. One limb of the tuning-fork carries a light style of sheet brass, which rests in light contact with the drum. As the drum revolves, and the tuning-fork vibrates, a wavy line is a traced upon the paper. The number of waves in any length is a measure of the time taken by the drum in turning through a corresponding angle."

Another method has been used with, it is said, considerable success, this consisting in illuminating the flywheel of the engine at regular intervals by means of an electric spark. If the sparking is perfectly regular, then, when the engine is

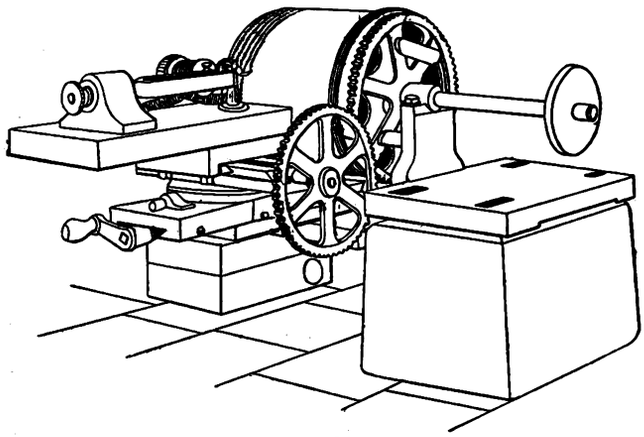

FIG. 81.

running also quite regularly, the spokes of the flywheel will appear to be stationary or else will appear to advance or recede at a regular rate; but if the engine alters in speed a corresponding change will take place in the successive displacements of the spokes, as revealed by the instantaneous sparks. The method is capable of considerable development; and the chief source of error which must be guarded against is liability to irregularity in the frequency of the sparks.

(To be continued.)

DANGER OF ELECTRIC SHOCK.

BY ALBION T. SNELL.

There appears to be much uncertainty in the minds of both experts and the public as regards the dangers of electric currents, and the decision of the Committee recently appointed by the Board of Trade to consider what shall be defined as high pressure does not seem to have met with general approval. Without questioning the wisdom of the decision arrived at by the eminent experts who have seen fit to place 500 continuous volts on a level, as regards danger, with 250 effective alternating volts, there does seem reason for asking upon what grounds the decision has been made. The extension of the maximum limit of low pressure continuous current supply to 500 volts appears to be warranted by comparative immunity hitherto from serious accidents in numerous plants in which a pressure of from 400 to 500 volts has long been used, chiefly for power purposes, but also for lighting in several supply stations.

Some ten years ago I had to select the pressure most suitable for large power plants in mines, and after a number of trials, both as regards the plant and the effects on the workmen, I fixed upon 500 volts as a convenient pressure, giving a sufficiently economic size of conductor, causing no serious trouble from leakage difficulties, and also, so far as my experience went, likely to occasion no serious accidents from shock *under working conditions*. In fact, the worst that have come to my notice during the past ten years have been small burns and shocks, which though unpleasant at the time, have resulted in no lasting damage.

I have had no special opportunity of studying the effects of a 500-volt shock on the human subject with contacts arranged to reduce the resistance of the skin to the lowest limits; but I have seen men with their boots soaked with water, and thus making good earth, knocked down by accidental contact with the conductor which happened to be insulated at the time. Speaking from my own experience and observation, I do not think that the strongest man could live for many minutes when subjected to a 500-volt current through good contacts. Fortunately in power work the conditions are usually well understood, and the plant is shielded from all persons except those in charge, who, of course, have to take their chance of a well-recognised danger, for which there are proper safeguards. It is due to these conditions rather than to any inherent safety of the 500-volt pressure that accidents are practically unknown in mines using electric power.

As regards the use of this pressure in buildings off the mains of a supply company, I have grave doubts, and the Committee of experts have also apparently viewed the matter with cautious reserve, for they advise the earthing of the middle wire of a three or five-wire system of mains, so that the maximum difference of pressure between any part of a consumer's electric fittings and earth cannot exceed 250 volts. In such cases we have to bear in mind that the switches, &c., are not to be handled exclusively by more or less skilled men, who know at least to some extent the danger of a shock, but these fittings are liable to be touched daily and at all hours by our wives, our servants, and even by chance our children. The question arises: Is a pressure of 250 volts, even if continuous, likely to be harmless to the ordinary user of electricity? I think it will be difficult to answer this question off-hand in the affirmative. In Manchester and St. Pancras the five-wire system has worked admirably, and there have been no complaints of serious shocks so far as I know, but surely no one denies the possibility of their happening at any time. I am not an alarmist, and have handled alternating pressures of 12,000 volts, but then I know the necessity for caution. *Apropos* of the dangers of a 250 volt continuous current, I recollect that a linesman had his hand burnt very badly in a mine where the pressure was about 235 volts, and the return conductor was a bare iron rope laid along a wet road; and, if my memory serves me rightly, a lad got hold of the positive conductor one day, and had to be dragged away by force, having lost the power of unclenching his fingers.

It does not appear quite clear whether the Committee recommended a pressure of 250 effective alternating volts as the maximum to be allowed within a building, or whether the old limit of 125 volts is to be retained. For my part, I do not think that our present knowledge of the physiological effects of electric currents warrants the drawing of a difference between continuous and alternating currents, so far as danger to life is concerned. Indeed, judging from accidents which have come under my notice, and also from a number of personal experiences incidental to my work, I believe the alternate current to be the least dangerous, on account of the well recognised repellant action on the fingers, whereas continuous currents contract them. Of course, if one falls on a conductor charged by either a continuous or an alternating current there may be little chance of escape unless help be at hand.

I am glad to find the Committee recommend that the middle wire of a three- or a five-wire system be earthed at one spot. This is the only way of fixing the maximum pressure on a given system of mains, and it gives the best possible safeguard against danger to workmen engaged on line work, because the limiting pressure is known. It is also important to the users of electric power, for it permits of the use of concentric wiring with an earthed outer—on three-wire systems at any rate—although its use would not appear to be feasible on a five-wire system, except in houses wired between the earthed centre main and one of the two adjacent mains.

THE GLOW LAMP QUESTION IN GERMANY.*

It is a general experience, and one which is confirmed almost every day, that glow lamps at present in the market are not, with regard to quality and life, all that could be desired. Since electric light has found a wider application little has been done which could be described as real improvements in glow lamp manufacture. Of course the price of lamps is at present only $\frac{1}{10}$th of the price of 10 or 12 years ago, when it was about 6s., but unfortunately this

* Report of a Commitee of Representatives of German Electric Supply Undertakings. From the *Elektrotechnische Zeitschrift* of December 5th.

Digitized by Google

reduction in the price has been made at the expense of the quality. It can certainly not be said that the watt consumption has not become less than it was 10 to 12 years ago, and it must be borne in mind that the life of lamps has fallen considerably. As it is of great importance to electric supply undertakings to have good lamps in order to prevent the electric light from coming into disrepute, it was the duty of the Committee to find out a way to always furnish consumers with good lamps, and by which makers could be compelled to supply good lamps.

The first question was, first of all, to settle what faults did lamps possess. With regard to this the Committee made a number of tests and asked for information from various sources. It would, however, take too much space to describe all the experiments in detail, and hence only the results will be considered. In general, these experiments have shown that the complaint of consumers. viz., the lamps were bad and of no value, are quite justified. The reason for this is careless sorting, careless marking, low efficiency, and short life. Every electrician who is accustomed to make photometrical tests will have found that the sorting and marking of lamps of nearly all makers leaves much to be desired. In fact, nearly always candle power and watt consumption differs from the figures guaranteed.

Tests made on about 70 16-c.p. lamps for 110 volts, and supplied by eight different German firms, showed a variation in the candle-power from 7·82 to 22·85 c.p. (*Normal-Kerze*). While the lamps were marked for a watt consumption of 3½ to 3½ watts per candle, the current absorbed varied from 0·43 to 0·63 ampere, and the watt consumption per candle from 2·8 to 6·3 watts.

Tests made on another 20 16-c.p. lamps for 110 volts, supplied by a well-known firm, showed a variation in the candle-power of from 10·21 to 21·6 candles, or more than 50 per cent. These lamps were specially supplied for testing purposes, and consumed 4·1 watts per candle.

Of five 16 c.p. 3½ watt lamps by another well-known firm, which were picked out of a larger quantity, one gave out at once, another emitted only 10·21 c.p., a third 13·6, and the remainder 16·02 and 16·63 c.p. The average watt consumption was 3·7 watts per candle.

In the case of another 10 16 c.p. 110 volt lamps by a third well-known firm, which were also taken from a larger quantity, the candle-power ranged from 15·9 to 22 candles, and the average consumption was 3½ watts, but after 48 hours the candle-power had fallen by 40 to 60 per cent., while the average watt consumption had risen to 5·6 watts per candle.

In 2½ watt lamps examined the conditions were found to be the same. Only a few lamps gave one candle for every 2½ watts, and most makers supplied 3½ watt lamps as 2½ watt lamps without any scruple.

From the above it will be seen that, as a rule, figures given by lamp makers cannot be trusted, as it is just as likely one will get an 8 or a 20 c.p. lamp as the 16 c.p. lamp asked for. It might be thought that so large a variation in the candle-power could be detected at once, but everyone who has carried out photometrical work will know that even for a trained eye it is difficult to do so. The reason for this is mainly that the specific luminous power, *i.e.*, the luminous power per unit of surface is generally the same in lamps of different candle power. If a 16 c.p. lamp is placed into a group of 20 c.p. lamps of the same specific luminous power, then for most eyes it is difficult to observe the difference, and for the general public it is most likely impossible. If the sorting and marking of lamps is in a bad state, examinations of lamps as to economy and life show no better results.

When the cost of the electric light is compared with other kinds of lighting 3 to 3½ watts per candle is generally accepted as normal consumption. Formerly the German or English standard candle was always used, but now the "Hefner lamp," which is 10 to 12 per cent. smaller, is employed almost exclusively. Full advantage of this has been taken by lamp makers, who now mark the same lamps as 3 watts, which formerly were 3½ watt lamps. How difficult it is at the present time to obtain really good lamps, which require at the beginning less than 3½ watts per candle is known to all electricians. After 300 hours most lamps require 4 watts, and after 500 hours 4½ watts. Later the watt consumption runs up very quickly to 5 and 6 watts per candle, and sometimes even higher before the lamp has burned out. In inferior lamps the watt consumption rises after 100 hours to 5 to 5½ watts per candle. It is therefore entirely wrong to take the average consumption of energy at 3½ watts without regard to the decrease of brightness, but it will come nearer the actual figure if 4 to 5 watts is accepted, especially if we consider that most consumers do not renew lamps till they give out.

Lamps having a smaller consumption than 3 watts per candle, and 2½, 2, and 1½ watt lamps play at the present time a very small part, as owing to their very short life the saving in the consumption of energy does not outweigh the cost for the renewal of the lamps. The estimates of such lamps, furnished by their makers, are usually only of theoretical interest, as the life is generally taken too long, and the candle power and watt consumption, which form the basis of these calculations, only apply to the first few hours. For an independent calculation we require to know the curves for light and energy consumption for the whole life of the lamp in order to be able to arrive at the average consumption. If this be done a quite different result is obtained, which also is far more in favour of the 3 and 3½ watt lamps. Further, experience teaches that at the present time the use of 3 watt lamps is the most advisable and the most profitable.

With regard to the life of lamps, this is found very different in lamps of different makers. Generally 800 to 1,000 hours is given for 3 to 3½ watt lamps. Formerly 1,000 hours was the usual figure, but this has now been somewhat reduced. Less than 800 hours is however not given as a rule. Such life can easily be attained in high vacuum lamps when life is understood to be the time from the first use of the lamp to the giving out of the same. On several occasions lives of 1,500 to 2,000 hours have been obtained. Such figures are, however, of absolutely no value, as all lamps before giving out have already reached a small candle-power and are inefficient.

By "life" the "useful life" (*Relative Brennzeit*) should always be understood, that is to say, the time which the candle-power of the lamp takes to fall a certain percentage. This percentage would be about right when taken at 20 per cent., and lamps, the candle-power of which has fallen that amount, should considered used up.

By a "candle-power" the "mean candle-power" should be understood measured in two directions vertical to each other. The candle-power varies, as is well known, according to the position of the lamps, and can vary as much as 20 per cent. between two positions. It is difficult to say in which position a lamp possesses its largest candle power, even if the lamps are of the same kind. It will be nearly correct if the lamp is placed in such a position on the photometer that an imaginary straight line passing through the terminals of the filament is at right angles to the photometer bench. By "mean candle-power" will then be understood the average attained by this measurement, and a second one in which the imaginary line is rotated through 90°.

If this "useful life" and "mean candle-power" be employed for calculations, then bad results are obtained with all lamps at present in the market. As an instance, it may be mentioned that in 10 16 c.p. 3½ watt lamps by well-known makers the average actual life was 1,450 hours and six lamps even attained a life of over 2,000 hours. The "useful life," however, was only about 400 hours. Five lamps of the same size by another maker had an actual life of 741 hours and a "useful life" of 366 hours. Ten lamps of the same size by a third firm gave an average actual life of 1,435 hours, six lamps burned for more than 2,000 hours, the "useful life," however, was only 150 hours. If from this two extra good lamps are deducted, the actual life was only 680 and the useful life only 17 hours. If lamps of the better class firms show such results, what may be expected of small makers? As a general rule their lamps must obviously be less economical and have a shorter life. The same holds good for lamps with a watt consumption of 3 watts and less. Seldom does the average "useful life" rise higher than 100 hours and the actual life higher than 300 to 400 hours. There are, however, a few exceptions, especially when makers know that the lamps are to be tested after delivery. What is mentioned here therefore applies to lamps sold in the market.

In ordinary lamps, such as consumers buy in shops, the "useful life" should never be taken above 400 hours, and, therefore, in calculation this figure should be employed instead of 800 to 1,000 hours.

It is remarkable that glow lamps, during the 15 years of their existence, have not improved, but rather deteriorated. The reason for this state of things is not difficult to discover. With the rapid development of the electric light the demand for lamps rose enormously. In consequence the makers were able to pay but little attention to careful manufacture; rapid manufacture was needed to meet the increased demand. This great demand for lamps resulted in the erection of a great number of lamp factories, the owners of which, without much preliminary knowledge, and without paying heed to the requirements of a good glow lamp, swamped the market with a cheap make, and forced the older manufacturers to reduce their prices also. Severe competition brought the price gradually down to one-tenth of the original price, so that even honest firms, who had the desire to introduce improvements and to carefully sort lamps, had to give up their good work if they wished to make a little profit on their work. Again, the ordinary consumer knows, as a rule, little as to how to judge the candle-power and economy of a lamp, and relies upon the promises made by the seller who sells the cheapest article. And frequently the seller is not very particular as to the voltage of his lamps, and then complaints are made to Electricity Works of insufficient pressure, while all the time it is no fault of the supply station. It is therefore of great importance to furnish consumers with the best possible lamps, as otherwise they might be driven back to gas, the more so as electric light is still more expensive than gas light.

Digitized by Google

In the last few years great efforts have been made in the gas industry to improve burners, and it is well known that the Auer burner has been of great advantage to gas companies. Electricity Works would profit in the same way if their whole influence was brought to bear on the manufacture and supply of good lamps. At all events, every pressure should be brought to bear in order to gradually suppress the large quantity of inferior stuff now in the market; only good lamps should be allowed, even if a rise in the price should be the consequence.

The question is now, what can electric supply undertakers do to attain this end? The Committee is of opinion that it could be more easily achieved than is perhaps thought possible.

First of all, Electricity Works must take the supply of lamps to consumers into their own hands, as was formerly the custom, and is still done by a few supply stations, and must not allow any lamps bought elsewhere. This could be done by either selling lamps at such a low figure that ordinary sellers could not compete, or, what would be better still, by following the example of Altona and Mulhouse, and supplying lamps gratis. It certainly does not suffice for Electricity Works to supply good lamps at the same price as the ordinary seller, unless no connection is made until the consumer signs an agreement only to buy lamps of the Company. But as electric light undertakers cannot very well indulge in much advertising, an agreement of the kind mentioned would arouse in the already suspicious consumer a suspicion that large profits were connected with the sale of glow lamps. The only way out of the difficulty is to supply lamps free of charge, or at least very cheap, perhaps below the cost price. The cost of such a gratuitous supply of lamps, which appears larger than it actually is, could easily be born by every electric supply concern, as it would not exceed 2 to 3 per cent. of the income derived from the sale of current. This loss would, however, be amply compensated by the increase in the number of consumers. There can be no doubt that by such a measure the electric light would gain in popularity. No inferior lamps, which are at present only kept on for reasons of economy, would be about, and all complaints and disagreeable remarks about the electric light would disappear, and better relations between consumer and supplier would be attained.

There is, however, one condition without which the matter could not be brought to a successful issue, and that is, Electricity Works must continually test and examine the lamps supplied by the manufacturer, and reject everything which is not in accordance with specification. Only a concerted move can effectively influence the manufacture of lamps, and to this end the Committee has drawn up a number of rules which may serve as a basis for contracts for the supply of lamps.

Specification for the Supply of Glow Lamps.

(1). Glow lamps must have on a test the required voltage and candle-power as well as the required watt consumption per unit of light. A variation is, however, permitted:—Voltage $\pm$ 2 per cent.; candle-power $\pm$ 6 per cent.; watt-consumption $\pm$ 6 per cent. All lamps which are not in accordance with these conditions are to be returned. Also lamps which show other faults or are badly mounted.

(2). The lamp supplier, in his tender, has to give a binding declaration as to the "useful life" of the lamps tendered. By "useful life" is to be understood the number of hours of burning in which the candle-power falls on an average by 20 per cent. of the original value. The watt consumption at the end of the "useful life" must not have increased more than 25 per cent. As unit of light the Hefner lamp will be taken.

(3). Tests are to be made in the laboratory of the Electricity Works, but can also, if desired by the lamp maker, be made at his cost at the Reichsanstalt. The fundamental conditions of the test are, however, to remain the same. Before delivery the maker must decide whether the test is to be made by the Reichsanstalt or the Electricity Works. When this is decided neither side can afterwards appeal. If the test be made in the testing department of the Electricity Works, the instruments of the same are to be considered as standards, but the lamp maker has the right to have the instruments tested from time to time.

(4). The test for the determination of the "useful life" is to be made in the following way: (*a*) Of each lot of lamps 1 per cent. is to be taken out for test; at least five lamps, however, must be taken. These lamps are to be tested photometrically at the beginning and at the end of the guaranteed "useful life." (*b*) The test is, if possible, to be made without stoppage, and the lamps are to stand upright or be suspended. (*c*) The lamps are to be tested photometrically either standing upright or suspending vertically, in such a fashion that an imaginary straight line passing through the connecting points of the filament coincides at one time with the longitudinal axis of the photometer bar, and the other time forms an angle of 90deg. with the same. The mean of the two tests is to determine the candle-power. (*d*) If one of the test lamps gives out during the first 24 hours it can be replaced by another one. No other lamps giving out before the end of the test can be replaced.

(5). The guarantee given by the seller with regard to the life of the lamps is to be considered as fulfilled, if after the expiry of the agreed "useful life" the sum of the candle-powers of all the test lamps has not diminished more than 20 per cent. of the original figure, and the watt consumption per unit of light has not increased more than 25 per cent. of the original.

THE CONTINUOUS RAIL IN STREET RAILWAY PRACTICE.*

BY RICHARD M'CULLOCH.

In the horse-car days, flat tram-rail laid on stringers was used almost entirely, and when the girder rail was rolled it was supposed that all that could be desired in the way of track had been produced. But when electric cars were put on the horse-car tracks, and when the length of these cars was increased from 18ft. to 35ft., the weights from 5,000lb. to 24,000lb., the speeds from 8 to 20 miles per hour, and the headway decreased from 5min. to less than 1min., the rail manufacturer found himself a thorough sympathiser with Jules Verne's armour-plate maker. For every inch that he added to the depth of his girder rail, and for every improvement in its manufacture, an additional length was added to the car and an additional weight to the trucks and motors. The life of a girder rail is supposed to continue until the head becomes so worn that the flanges of the wheels begin to run on the tread. But as a matter of fact, few street railway tracks last until this takes place, for long before the head is worn off the joints have become so rough that the rail must be renewed to save wear and tear on passengers and cars.

Exactly who was the first man bold enough to suggest having no joints at all is hard to say, but it is pretty certain that the first experimenting in this line was done by Mr. Philip Noonan, a railroad engineer of Lynchburg, Va., who several years ago built about three miles of steam-railroad track leaving no openings between the rails and fastening the joints with hot-rivetted plates. This track was in actual use for several years, and was the first demonstration of the continuous rail. Early in 1892, the Johnson Company, of Johnstown., Pa., began experimenting with the continuous rail. One rail of a section of track 1,160ft. long was joined by heavy bars and machine-fitted bolts so that there was no possibility of movement. Carefully-fitted wedges were driven into the spaces between the ends of the rails, and every precaution taken to have the joint absolutely immoveable. The other rail of the same track was laid in the ordinary manner, with fish-plates and openings between the rails, so that any deviation of the continuous rail from a straight line would be noticed in the change of gauge. The rail used was the Johnson 6in. 78lb. girder, and the track was in actual use during the time of experimenting. At five points along the line stakes were set opposite marks on the rails, so that any change in the length of rail would at once be noticeable. During the period of experiment the air temperature varied from 10 to 89 deg., and absolutely no movement could be detected in the rails, either longitudinally or laterally. This experiment satisfied the Johnson Company that the continuous rail was practicable; and having proved its feasibility they at once set about finding the best method of uniting the rail ends.

The method adopted by this Company for connecting the rail ends was that of welding them electrically. A machine for this purpose was built by the Thomson Welding Company, and in the spring and summer of 1893, about three miles in Johnstown and about eight miles of track in Boston were electrically welded. During the winter of 1893-4 about 6 per cent. of these joints broke. Having remedied some apparent defects in the method, the Johnson Company in the spring of 1894 sent their machine to St. Louis, where 6½ miles of track were electrically welded. From St. Louis the machine was sent to Cleveland, where about 5 miles were welded, and then to Brooklyn, where 32 miles of track were joined together by this method. The first track electrically welded, that is, that in Johnstown and Boston, was not welded directly at the joint, but the rail ends were joined on each side by means of a span which was welded to the web of the rail about four inches back of the end. The breaks did not occur at the joint or in the span, but the rail itself broke where the span had been welded on. This was supposed to be due to the fact that when the rail at this point cooled after the welding process, internal strains were produced which seriously impaired the tensile strength of the rail at this point. A new form of joint was devised, by means of which an actual butt weld is made at the joint, and this is the method which has been applied in St. Louis.

The Baden Division of the St. Louis Railroad Company, where the electric welding in this city was done, consists of 3½ miles of

double track. The track throughout is laid in a macadam street, no paving being used either inside or outside the rail.

Cast Welding.

As soon as the fact was demonstrated that a continuous rail buried in the ground was a possibility, other methods besides the electric welding of the joints were proposed. The particular one which will be described here is what is known as the "cast-welding" process, and is being exploited by the Falk Manufacturing Company, of Milwaukee. This, to briefly describe it, consists of clasping the ends of the rails for about 8in. on each side of the joint by means of a mould, and then pouring the mould full of molten iron. The iron solidifies on the rails around the joint, and makes a partial union with it. In order to compare the two methods, the St. Louis Railroad Company, in the fall of 1894, had three miles of track in the southern part of the city connected by the cast-welded process. As the furnace was not ready at the time the rails were laid, the track work was finished and the trench filled in, leaving the joints temporarily connected by fish-plates. Some three months later, when the furnace arrived, the macadam around the joints was dug up, the fish-plates removed, and the rails united by means of the cast joint. The track was laid in July and August, and the rails were welded in October and November. No cars were operated over this track during the winter of 1894-95, but at present the cars of the South Western Railway are running regularly over this route. On account of the excellent record made by this track during last winter, the officers of the Citizens Railway Company, of this city, decided in relaying the old cable track, to use the cast-welded joint.

The apparatus for casting the joints consists of a cupola furnace mounted on a heavy truck. The cupola is 2ft. in diameter, brick-lined, and the blast is furnished by a No. 5 Sturtevant blower, driven at 1,800 revolutions per minute, by a 5 H.P. motor, which receives its current from the trolley. The cupola is operated as is usual in a foundry, and the iron used is one-half best soft gray pig and one-half selected scrap. The scrap consists of old gear wheels, manhole covers and frames, an abundance of which are found in the scrap heap of the railway. The furnace works very rapidly, and in 20 minutes after the blast is turned on the iron is ready to pour. It may then be tapped as long as the charging is continued at the top. The preparation of the joint for casting is as follows: The fish-plates are first taken off and the rail ends for about 8in. back polished with garnet paper. If there is any opening between the rails it is closed by shims. The moulds, consisting of two castings made to fit the rail, are then placed about the joint and clamped in position. A heavy clamp is placed on top of the rail and screwed up as tightly as possible to hold the joint immovable while being poured. This clamp is left on the rail until the casting has cooled. Preparatory to the pouring the moulds are lined with a mixture of linseed oil and plumbago, and are heated to drive out any moisture in them or on the rail. The pouring operation is very simple. The melted iron is run from the cupola into a ladle and then slowly poured into the mould. This final operation is very quickly performed, as it usually takes only about three hours to pour 40 joints. The casting weighs 137lb. and extends back on the rail 7in., taking in two of the bolt holes in the ends of the rails. In this way four bolts are cast through the rail. It is undoubtedly the case that a sort of welding action takes place between the iron and the steel rail, as on examination of a joint sawed in two it will be difficult to tell the exact junction of the iron and the steel.

Having described the modes of applying these two processes, let us see what they have done in actual operation. The Baden road, constructed in the spring of 1894, which had its rail ends connected by the electric method had, in all 2,203 joints, and of these 72, or 3·27 per cent., have broken. Thirty-seven broke during the cold weather of the first part of the winter, and these were repaired by the cast-welding method. During a later cold snap 35 more were broken. These have not yet been repaired. During the heat of the summer no trouble whatever was experienced with the alignment of the track. From the weather bureau reports the average temperature while the construction was in progress was 63deg., ranging from 14deg. as a minimum to 99deg. as a maximum. During the last winter the lowest temperature was 12deg. below zero, and the hottest day in the summer was 100deg., making the range of temperature through which the track has passed 112deg., or a maximum deviation from the average welding temperature of 75deg. Seven of the joints on breaking opened nearly 2in., but in many the opening was so small as barely to be perceptible, the average opening being about ¼in. During the warm weather of this summer the openings were diminished slightly, but the openings have never completely closed. Every joint which has broken has shown itself to be an imperfect weld. There has never yet been an instance of a good weld breaking. In all cases the rail ends have simply pulled apart, the lugs sticking to that rail which held them tightest. In a few instances small pieces of rail pulled off with the lugs, but in no cases have the rails themselves broken, and we have never had a joint to break which looked as if it had ever been really welded. There are several reasons for this. On account of the great distance from the power house, the voltage was necessarily low while the weld was being made. The work at that time was new and not very well understood; and the workmen who had the machine in charge were often careless and hurried. The result of this experiment is far from being discouraging, and the officers of the railway company are satisfied that with the additional knowledge we now possess, and with the improvements which have been made in the welding machine, by which a fairly constant voltage is maintained while the welding is in progress, that it is possible to construct a track by this method with an insignificant trouble from breakage.

In regard to experiments elsewhere, Mr. C. W. Wason, electrical engineer of the Cleveland Electric Railway Company, has been kind enough to furnish information as to results obtained in Cleveland. During the summer of 1894, 3,400 joints were made electrically, two-thirds of which were on 56lb. rail and the remainder on 90lb. rail. Of this number the total breakage during last winter was six, four of them being on 56lb rail and the remainder on 90lb. rail. The percentage of breakage was 0·18 per cent. which is a much better record than that made in St. Louis. All the joints which broke showed themselves to be imperfectly welded. Mr. Wason expresses himself as highly in favour of the electric method of welding, and states that the breaks and rough joints on his track were due to carelessness on the part of the workmen operating the machine.

The cast-welded track of the South-Western Railway on Chippewa-street was welded during the months of October and November of the same year. The average temperature while this work was in progress was 51deg., with a maximum of 84deg. and a minimum of 18deg. There were 744 joints in all, and during the winter only three, or 0·43 per cent., broke. As stated in the case of electric-welded track, no deviation whatever has been perceived in the alignment. Since this track was laid the temperature has ranged from 100deg. as a maximum to 12deg. below zero as a minimum—a range of 112deg. and a deviation of 63deg. from the welding temperature.

The Falk Manufacturing Company, who are making the cast joint, have this summer operated in Chicago, St. Paul, Minneapolis and Newark, besides the work done in St. Louis. In Chicago, for the Chicago City Railway, 11,903 joints were made on 4½in and 7in. rail, and for the West Chicago Street Railroad Company, 8,867 joints were made. In St. Paul, Minneapolis, and Newark, work has recently begun, and up to the present time about 2,000 joints have been made in each place. The results so far have been very satisfactory, both to the railroad companies and to the contractors.

It seems difficult to those accustomed to steam railroad tracks to reconcile themselves to the use of a continuous rail. They instinctively call to mind certain experiences they have had with rails creeping and getting out of place on account of temperature variations. It must be remembered, however, that street railway tracks differ in one very important particular from those of the steam railways, that is in having a road bed firmly packed about the rail. The perimeter of a 7in. rail is 29in. of which only 6½ or 22·4 per cent. is exposed to the air, while the remaining 67·6 per cent. is covered up and firmly gripped by the road-bed. No one can understand how firm this grip is who has not seen a rail which has lain in a macadam street several years taken up, when the whole buried surface of the rail is found to be covered with a hard cement composed of stones and mud requiring considerable work with a pick to remove. There is a great tendency on the part of the rail to change its length with the temperature variations, but there is also the ability of the road-bed to hold it in place.

The strain on rails due to the variations of temperature may be estimated as follows. Assuming a coefficient of expansion for steel of 0·0000065, and multiplying this by 75, which is a liberal figure for the number of degrees of maximum deviation from the welding temperature, we get 0·000487, which is that part of its length which a rail would expand due to a rise of 75 degrees, or contract due to a fall of 75 degrees in temperature. A steel bar will expand 0·00003 of its length due to a load of 1,000 pounds per square inch. Dividing the estimated expansion by this figure we get for the strain 16,200 pounds per square inch. As the rail is 8½ inches in cross section, the total pull due to a fall of 75deg. in temperature is 137,700lb. As 40,000lb. per sq. in. is a safe value for the elastic limit of steel it can readily be seen that in this climate at least the elastic limit will never be reached, and this means that these expansions and contractions may go on indefinitely, and as long as the joints remain unbroken no harm will be done to the rail, for it is a well-proven fact that stresses within the elastic limit work no harm. Assuming 80,000lb. per sq. in. as the ultimate strength of steel, we see that so far as the strength of the rails themselves is concerned, we have a factor of safety of five.

An interesting calculation may be made showing the friction with which the rail is held by the road-bed. Taking the figures for the contraction of the rail due to a fall of 75deg. in temperature,

D

Digitized by Google

each rail of the Baden track should have contracted 8ft. 6in. As a matter of fact, when the joints broke the openings in none of these exceeded 2in., and the combined openings of one rail the length of the road did not exceed 6in. This would seem to show that the pull which broke the joint was not a transmitted, cumulative effort extending all along the line, but was more the result of a local strain, not extending for a great distance on either side of the joint. Reasoning from the same data, it would appear that the strain at other points along the track has not been relieved, and that the joints at these other places have shown themselves strong enough to endure the pull.

The strength of the cast-iron joint may be shown to be fully equal to the strength of the rail. The area of its cross section at the joint is 61·6 sq. in. In order to make a perfectly safe estimate, let us assume that its cross section is reduced 25 per cent., or to 45 sq. in. by blow holes and imperfections. Taking for the tensile strength of cast iron 18,000lb. per sq. in., we have as the ultimate strength of the joint 810,000lb., which is largely in excess of the rail.

Comparison of Methods.

The two methods just described are the only processes of actualiy welding rails yet put into operation. The electric welding is scientifically a beautiful process, and when skilfully done we have no hesitation in saying that the joint is stronger than the rail itself. It has the disadvantage, however, of requiring considerable care and intelligence to operate it, qualifications which are sometimes difficult to find in workmen. It is also impossible to tell simply by looking at a joint whether or not it is really welded. On ordinary railway circuits when the voltage fluctuates continually it is difficult to operate the processes successfully. This, however, it is proposed to remedy by using a storage battery, which takes current from the line when the welding machine is idle, but which is thrown into parallel with the line and assists in maintaining the voltage while the welding is in progress. The welding machine with its accessories is exceedingly heavy and cumbersome, and difficult to move from place to place where track is not already laid. The great expense of an outfit prohibits almost any railroad company owning one and this complicates the question of repairs, for if the machine is gone and some of the joints break, how are they to be repaired?

Without wishing to make any invidious comparisons, it would be well to call attention to some of the advantages which the cast-welding process possesses. The first is, the relative simplicity and cheapness of the apparatus employed and the ease with which men may be procured who are used to this kind of work and capable of doing it well. The machine is not very heavy, it does not run on the track and can be transported easily and quickly from place to place. While as yet no difficulties have developed, the weak points of the process would seem to be: First, that the joint is a casting, subject to blowholes, chilling, imperfections and all the ills of a casting, any one which might greatly impair its tensile strength; and second, the fact that the steel rail and the cast-iron joint possess different coefficients of expansion, and that under variations in temperature internal strains might arise in the joint itself, which might finally result in its rupture. As has already been stated, however, no troubles of this kind have as yet developed, and these are merely considerations which suggest themselves in the examination of the process.

The cost of either of these methods is not greatly in excess of the old fish-plate method; but even if it was, the advantages gained by the abolition of joints would be of such value that no progressive railroad man would hesitate on that account. If either method will remedy for all time trouble with joints, the cost of repairs to the track after being down a few years, if laid with fish-plates, would soon pay the extra first cost, without considering the prolonged life of the rolling stock, and the prestige given to the road on account of its smooth riding track. If joints are abolished, the life of a track instead of being limited by the life of the joints will be the life of the rail itself, and this will far outweigh any considerations as to the cost of making the joints.

An additional advantage which should be mentioned is that any form of welding obviates the necessity of bonding the joints of electric roads. Tests which have been made on welded joints show that the electric conductivity of the joint is as great as that of the rail itself. Assuming the conductivity of steel to be one-seventh that of copper, an 85lb. steel rail would have a carrying capacity equal to a copper bar 1·2 sq. in. in section, or, as feed wire is usually rated, of 1,500,000 circular mils. A double track, consisting of four of these rails, would thus have a conductivity equal to 6,000,000 circular mils. This is largely in excess of the feeder section of any one line of railway in St. Louis. For instance, the combined section of the feeders which run to the Citizen's line, which was calculaied for 60 cars allowing a drop of 50 volts at full load, is 3,200,000 circular mils. To one who is engaged in the actual operation of street railways this means a great deal. Given a track with a conductivity equal to that just cited, it is necessary only to establish a low-resistance connection between the rails and the 'bus bar in the power house, when all the troubles due to low voltage along the line, and all the dangers of electrolysis, would be a thing of the past.

It is not to be supposed that the millennium in track-construction has already been reached, but what has been demonstrated is this: First, that the use of a continuous rail for street-railway practice is feasible, and, second, that it is possible to make joints of sufficient strength to stand changes of temperature.

NEW PUBLIC COMPANIES OF 1895.

The following are the more important limited liability companies connected with the electrical engineering and allied industries registered during the past year, with their capital:—

	Capital.
Acetylene Illuminating Company	£21,900
Alliance Meter Company	5,000
Alternate Current Electromotor Syndicate	6,000
Amazon Telegraph Company	250,000
Apostoloff Automatic Telephone Patent Syndicate	10,000
Automatic Electric Sign Company	5,000
Automotive Syndicate	5,000
Bartlett (J. G.) and Co.	20,000
Battery and Motor Company	12,000
Bentley and Jackson	40,000
"Best" Miners' Safety Lamp Company	25,000
British Electric Traction (Pioneer) Company	100,000
British Electrical Manufacturing and Engineering Company	20,000
British Electrozone Corporation	250,000
British Motor Syndicate	150,000
Broadbent (Thomas) and Sons	25,000
Capital and Counties Electricity Supply Company	5,000
Cambridge Scientific Instrument Company	10,000
Celline Art Metal Works	5,000
Cheshire Electric and Steam Yacht Company	2,000
Connolly Brothers	20,000
Cork Electric Light and Power Company	1,000
County of London Tramways Syndicate	5,000
Cramp Manganese Bronze Company of Great Britain	50,000
Davy Electrical Construction Company	10,000
Direct Electric Generator Syndicate	100,000
"D.P." Battery Company	10,000
Douglas Southern Electric Tramways	50,000
Electric and General Exploring Syndicate	5,000
Electric Guest Call Company	5,000
Electric Installation Syndicate	5,000
Electric Organ Company	110,000
Electric Ozone Syndicate	12,000
Electric Sign and General Advertising Company	5,000
Elliott's Moulding and Joinery Company	30,000
Electrical Oil Refining Company	5,000
Electrolytic Research Syndicate	1,000
Empire Economic Steam Producer Company	80,000
English Automobile Horseless Carriage Syndicate	5,000
Evans, O'Donnell and Co.	45,000
Evershed and Vignoles	10,000
Farmer (Sir James) and Sons	15,000
Fielding and Platt	50,000
Fort William Electric Lighting Company	7,000
Galloways	115,000
General Electric Tramways Company	50,000
General Traction Company	50,000
Gilbert Gilkes and Co	£20,000
Grenfell, Hubert	12,500
Harrington Electric Light Company	3,000
Harrow Electric Light and Power Company	25,000
Headland's Patent Electric Storage Battery Company	15,000
Horseless Carriage and Motor Cycle Company	100
Howell (J. C.) and Co.	10,000
I.E.S. Accumulator Company	100,000
Improved Electric Glow Lamp Syndicate	5,000
Industrial Inventions Development Company	50,000
Irwell Rubber Company	30,000
Jandus Arc Lamp and Electric Company	20,000
Johnson Miners' Safety Lamp Company	5,000
Keighley Electrical Engineering Company	5,000
Lamp Manufacturing Company	20,000
Lightning Express Railway Syndicate	100,000
Lighting Corporation	250,000
Liverpool District Lighting Company	2,000
London and Provincial Traction Company	100,100
Machinery Insurance Company	200,000
Madeira Electric Lighting Company	20,000
Magic Box Company	5,000
May's Metals Separating Syndicate	2,000
Manchester Suburban Electric Supply Company	25,000
Mevagissey Electric Lighting Company	1,500
McPhail and Simpson's Dry Steam Patents Company	416,000
Milver Portable Electric Battery Syndicate	20,000
New Electric Light Syndicate	2,000
Newmarket Electric Light Company	30,000

Sykes (Robert) and Sons	20,000
Telautograph Company	42,000
Thames Valley Launch Company	10,000
Town and Village Electric Light and Power Company	100,000
Tramways Construction Company	100,000
Tramways Electrical Traction Company	172,500
Tupper's Advertising Company	2,000
Universal Electric Carriage Syndicate	5,000
Universal Electrical Fittings Company	6,000
Val d'Aosta Electric Power Company	80,000
Vaughan and Brown	40,000
West Australian Electrical Trunk Power and Lighting Company	510,000
Westralian Electric Lighting and Supply Company	80,000
Wheeler Hill	62,500
Windsor Electrical Installation Company	10,000
Wilson (E. K.) and Sons	12,000
Woking Electric Supply Company	20,000

PUBLIC COMPANIES WOUND UP, DISSOLVED, &c., IN 1895.

The following are amongst the limited liability companies which have been wound up during the past year, the asterisk denoting that the company was wound up by order of the Court :—

Akester Electric Syndicate.
Albert Lighting Company.
British Volta Glow Lamp Company.
Collier-Marr Telephone and Electrical Manufacturing Company.
Electric Lighting and General Development Syndicate.
Electric Trust.
Electrolytic Caustic Soda and Chlorine Trust.
European Sims-Edison Electrical Torpedo Company.
Farmer (Sir James) and Sons.
Forbes (D. W.) and Co.
*Ford-Lloyd Manufacturing Company.
Froggatt's Electric Lighting Company.
Galloways (*reconstructed*).
Hemming and Co.
*Herculite and Electrical Manufacturing Company.
Hope-Jones Electric Organ Company.
Howell, J. C. (*reconstructed*).
Hughes, Sutton and Digby.
International Electric Storage.
Inventions Development Syndicate.
Johannesburg Lighting Company.
Keighley Electrical Engineering Company (*reconstructed*).
Planet Electrical Engineering Company.
Lamp Manufacturing Company (*reconstructed*).
Lowcock, Hill and Co.
*Medical Electrical Institute.
*Martiny Limited.
Metallurgical Patents Company.
*New British Electrical Installation Contractors.
Otis Steel Company.
Printing Telegraph and Construction Company of the Agence Havas.
Railway Automatic Electric Light Syndicate.
*Scott, Ronald A.
St. Martin's Electrical Manufacturing Company.
Telpher Cable and Cliffe Railway Syndicate.
*J. G. Statter and Co.
Universal Electric Lighting Company.
Wray Electrical Engineering Company.

The following companies have been dissolved, or have ceased to exist, in most cases nothing having been done beyond registration, and no business having been commenced :—

Association for the Protection of Telephone Subscribers.
Baily and Grundy (London).
Bicester Electricity Supply Company.
Bishop's Stortford Electric Light and Steam Laundry Company.
Boardman's Electric Sun Lamp Patents.
British Electrolytic Syndicate.
British Electric Tramways and General Syndicate.
Brompton Electrical Fittings Company.
Cambridge University and Town Electric Lighting Company.
Carbon Electric.
Central Electrical Company.
City of Waterford Electric Supply Company.
Croydon Electric Supply Company.
Devonshire Electric Light and Power Supply.
Dominion Electrical Company.
East Coast Electric Light and Power Supply.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, January 6th.

SOCIETY OF CHEMICAL INDUSTRY.
8 p.m. Meeting at Burlington House.

SATURDAY, January 11th.

ASSOCIATION FOR THE IMPROVEMENT OF GEOMETRICAL TEACHING.
11 a.m and 2 p.m. Meeting at University College, Gower-street.

Electricity and Vegetation.—Two important Papers, says *Nature*, have recently been published on the effect of the electric light and of electricity on vegetation. The first is by M. Bonnier in the *Revue Générale de Botanique*. He states that a continuous electric light promotes the formation of chlorophyll, and brings about, at the same time, a simpler anatomical structure of the leaves. Under a continuous electric light the distribution of the chlorophyll in the tissues is more extended than in ordinary daylight; chlorophyll grains make their appearance in the cortex as far as the endoderm, and even in the medullary rays and the pith. The palisade tissue of the leaf is reduced, or entirely disappears, and the epidermall cell walls are thinner. The bark is less developed, and the various tissues of the stem are less differentiated. When the electric light is discontinuous, as, for example, when turned on 12 hours out of the 24, the effect on vegetation is intermediate between that of normal sunlight and that of a continuous electric light. Alpine plants cultivated under a continuous electric light exhibit points of structure identical with those of Arctic plants, which are exposed to almost continuous sunlight in the summer. The other Paper is by Prof. A. Aloi in the *Bulletino* of the Italian Botanical Society. He adduces evidence in favour of his view that both terrestrial and atmospheric electricity exercise a favourable influence on the germination of seeds and on the growth of plants, and predicts that the employment of electricity will be a most important factor in the agriculture of the future.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

ublished every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 8d., post free, 8½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. *[In preparation.*

FULL CATALOGUE POST FREE ON APPLICATION.

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d, post free 13s. 6d. Many of these Volumes are very scarce.

NOTICE.

With the current number of "The Electrician" is issued as a Supplement (Gratis) a Tabulated Statement, giving complete details of Electric Supply Stations in London and the Provinces; showing at a glance towns in which the Electric Light is supplied, either by a Local Authority or Private Company, and the System adopted (Continuous or Alternate-Current), &c., &c Complaints of non-receipt should be at once sent to the Publisher.

Extra Copies of this Sheet can be obtained (post free), price 2s., or mounted for hanging, price 4s. varnished, unvarnished 3s. 6d.

1895.

In accordance with an inexorable custom, we once more devote the first leading article of the New Year to a review of the electrical events of the Old Year. Time was when our annual offering consisted mainly of a string of reports on the past year's work, supplied by the comparatively small group of firms which then constituted the entire English electrical industry. The tone of genial optimism which uniformly characterised these returns, even in the days of deepest commercial depression, did credit to the stoicism and businesslike diplomacy of their compilers; but as reliable historical records they were not all one could wish. To-day, were we to attempt the same style of disjointed chronicle, its size would be truly monumental; a conclusive, if not an altogether pleasing, evidence of growth. Yes; quiet prosaic progress has been the predominant feature of 1895 as of its immediate predecessors. For the moment the purely scientific electrician is outwardly somnolent, and the electrical engineer proper makes no effort to disguise the fact that he has eschewed the evil habits of his early youth; he has slackened his hot pursuit after mechanical and electrical novelties, and has betaken himself to devising economical and efficient combinations of "old instrumentalities"; his talk is of 220-volt lamps and the earthing of the "neutral," and his mind is in labour with cunning methods of charging his customers and with plans for defeating the devious ways of jerry wirers.

Digitized by Google

The main element of growth in the electrical industry still continues to be afforded by the electric light supply business. New stations continue to come steadily into operation, and old ones continue to add steadily to their lamp connection. Neither the cost price nor the selling price of the Board of Trade unit has as yet found bottom, and the return upon capital expenditure, especially in the case of provincial municipal ventures, is most encouraging. Amongst the more important municipal stations that have got to work during the past twelvemonth we may mention those at Belfast, Blackburn, Coventry, Edinburgh, Leicester, Newport, Salford, Stafford, Sunderland and Tunbridge Wells. One of the most noteworthy events in connection with central-station enterprise has been the 220-volt lamp crusade. Inspired apparently by Mr. BAYNES' vigorous initiative, first at Bradford and then at St. Pancras, those responsible for the success of electric supply undertakings have with one accord declared that the salvation of "low-pressure" systems lies in the adoption of what is uncommonly like "high pressure," and the expert committee—that after-math of the recent Board of Trade Conference at Westminster—has complaisantly decided to recommend the Department to swim with the stream, and to allow 250-volt pressures inside houses and 500 volts (continuous) across "outers," and to concede at the same time the long-urged demand for the earthing of the "neutral." There are, of course, restrictions and conditions attached to these unexpected concessions, and there are, too, some who are disposed, so long as these restrictions and conditions are maintained, to accept the concessions in a grudging spirit. However, the principle of high "low pressures" and earthing the "neutral" once accepted by the powers that be, it is improbable that on either side there will be much difficulty as to details. Indeed, the only point which seems in any way likely to threaten the almost angelic harmony now prevailing between the Board of Trade and those under its benign jurisdiction is the undue penalisation of low-pressure alternating currents which the Department seems inclined to impose. The anger of an Englishman quickly subsides if his advice is asked and his grievances are freely aired. The inevitable red-tape tendencies of a Government Department can only be counteracted by contact with men and things as they exist outside. Penetrated with these two ideas, Sir COURTENAY BOYLE's relations with the electrical industry have not been the least of his administrative successes.

In central-station practice there has been, during the past twelve-month, a marked tendency to combine an alternating system for outlying districts with continuous current for the central area, motor-alternators being usually employed. Mr. FERRANTI's bold expedient of rectifying alternating currents for use in street arc lights is also finding great favour with alternate-current station engineers,—photometric measurements, indoors and out, rendering it evident to all unbiassed persons that the alternate-current arc can scarcely hold its own against good modern gas lighting, not to mention its more regular electrical rival. Another combination which bids fair to become an integral feature of all fashionable English municipal central stations is that of dust destruction and steam raising for electrical purposes. Enough has recently been vaticinated as to the advantages of this idea. By this time next year data garnered from actual experience may possibly be available, and further discussion will then be profitable. Not the least valuable of the many recent discoveries in central-station economies is the method—hit upon by Mr. ARTHUR WRIGHT, and rendered possible by his cheap and simple demand-meter—of charging the consumer for current in such a manner that it pays *him* (and consequently the central station) to burn comparatively few lamps fairly continuously, rather than big banks of lamps in spasmodic bursts. The sweet-reasonableness of the "Wright" system of charging has now become evident to all, and its adoption is becoming general in the provinces. The annals of the central-station industry are not, however, without a reverse to the pleasant obverse just briefly sketched. Two serious fires at large London generating centres and another at a small provincial station show that more consideration requires to be given to fireproof construction and to fire drill. It will never do for English electric light stations to earn the bad name their American congeners have acquired for themselves. The difficulties of stations situated in crowded districts are already sufficiently great without this additional burden. The discovery also that metallic sodium and potassium had been electrolytically formed in the St. Pancras conduits was not calculated to make glad the heart of the electrical engineer, nor to decrease the feeling of insecurity engendered in that favoured neighbourhood by recurring explosions. Investigation, however, showed that the peculiar conditions which obtained in a portion of the St. Pancras conduits were alone to blame. The public alarm soon subsided, and with the carrying out of the needful remedies the only saleable by-product of the central station has ceased to be formed.

Electric traction still tarries—retarded, may be, by the recent extension of the Monroe doctrine to all things that even so much as smack of America. An interesting mountain railway was opened in August in the Isle of Man, and two months later the Bristol-Kingswood line was inaugurated amidst the blowing of trumpets and the beating of drums, the echoes of which have scarcely yet died away. These two enterprises, plus a few miles of track at Coventry, represent the sum total of our achievements in electric traction during the past twelve months. Of work actually in hand the line between Dublin and Dalkey and the line at Hartlepool are in the most forward stage. The Central London Railway has (at last) been commenced, and the Waterloo and City tunnel is stealthily burrowing its way under river and road. But the half-dozen other London electric lines are in the same state of suspended animation that they were this time last year. *Per contra*, the air is thick with electric traction "proposals," the most important and the most likely to come to maturity being, perhaps, those entertained by the Leeds City Council. The Tramway Act of 1870 and the recent judicial pronouncements as to the exact meaning of its purchase clause have obviously rendered tramway development in this country almost impossible unless under municipal ægis. There are signs that our municipalities are awakening to the fact that they cannot in common justice continue indefinitely to arrest private tramway enterprise without supplying a municipal equivalent, and there are unmistakable indications that in the coming rush those who have for years preached the advantages of electric traction to deaf ears will get a hearing. We can only hope, firstly, that those who have sown will reap; and, secondly, that we English will take full advantage of the experience bought at such a high price across the Atlantic. There is no need for *us* to grope our way in a blind, haphazard fashion towards the best type of truck, track, gearing, motor-suspension, line, generator and engine.

The materials for a telegraphic chronicle have in the past year, as previously, been supplied by the submarine branch. A few weeks since the "Faraday" left the Thames laden with the cable which is to form a telegraphic network connecting the various rubber stations along the banks of the Amazon from Para to Manaos. The whole scheme is somewhat of an experiment though a very interesting one, it is true. Amongst

Digitized by Google

other things it is proposed to make considerable use of the telephone as a means of transmission, in order to avoid as far as possible the expense of skilled operators. Another event of note was the signing, early in October, of a contract between the French Government and the Compagnie Française des Câbles Télégraphiques for the laying and working of a new direct French-made French-laid transatlantic cable from Brest to Cape Cod. It is also proposed to lay a cable connecting the French transatlantic cable system with the French West Indian cable system, and generally to render France, as far as may be, telegraphically self-supporting. Whether the thing is possible, and if possible, whether the game is worth the candle, it is for our "*bons voisins*" to decide—and pay the piper. In English cable circles we may further note the remarkable growth of the Australasian traffic, which has brought the revenue derived therefrom back once more to the figure at which it stood before the wholesale reductions made some years ago under Government guarantee, and the deputation to Mr. Chamberlain anent the Pacific cable scheme, with its resultant promise of an Imperial Commission to inquire into the whole question. In connection with submarine telegraphy it will not be out of place to recall here the commercial utilisation of "induction" telegraphy which was made in April last when the cable broke down between the Isle of Mull and the mainland, and the successful establishment and maintenance of telegraphic communication with the Fastnet Rock on the "discontinuous cable" system. Automatic working also, is coming rapidly to the fore, and notwithstanding the apparent quiet, plenty of progressive technical work is being done in the submarine cable world.

In the telephonic branch of the electrical industry there is not much technical advance to be chronicled. Early in the year the municipalities lodged protest after protest against the signing of the Agreement between the Post Office and the National Telephone Company. Finally, on March 1st, the Postmaster-General consented, under pressure, to the appointment of a Committee, not to discuss the Agreement, which the Government "could not, and ought not, to consider other than a binding obligation," but "to consider and report whether the provision now made as to the telephone service in local areas is adequate, and whether it is expedient to supplement or improve this provision either by the granting of licences to the Local Authorities or otherwise." The proceedings of this Committee opened on March 22nd, and the Committee reported formally to the House on June 15th, suggesting nothing but its own reappointment this year. The Post Office view of the question and the National Telephone Company's view were admirably presented, but the case for municipal exchanges and national trunk lines, for which so much can be said, was very inadequately set forth, and, if the inquiry is ever resumed, it is to be hoped the supporters of this idea will see to it that arguments calculated to carry weight are forthcoming. In this relation it is curious to observe how the trend of fashion is forcing the great practical applications of electricity one by one into the hands of Government and municipaldom. The telegraph was born and attained a healthy maturity under the invigorating influence of capitalist competition. The Government in 1870 seized upon it, and straightway all the life went out of the business. The telephone arose next, under much the same influence. The Government promptly claimed it as its own, and the courts of law upheld the claim, and officialdom and monopoly have between them rendered all outward manifestation of life and progress impossible. Then the electric light came upon the scene. Private capital gave this also an initiatory impulse, but, thanks to the Act of 1882, the municipalites are rapidly taking up the running. Lastly, some five years ago, electric traction began to make decided progress in the United States, and then tried to force an entrance into this country. Once again, thanks to the paralysing influence of the Tramway Act of 1870, private enterprise is being kept at arm's length, and it is now beginning to be generally recognised that if we are to have electric tramways at all, we shall be obliged to accept them at the hands of the municipalities. Prof. Vernon Boys remarked the other evening at the Society of Arts, in connection with horseless carriages that, "the community at large are not competent to form an opinion upon conditions of life which differ widely from those to which they are accustomed," and we will not, therefore, risk a prophecy as to the probable net ultimate result of this nationalisation and municipalisation of electrical engineering. One institution, however, we feel sure will be completely transmogrified. All the members of the Institution of Electrical Engineers will *then* be as tongue-tied as its telegraphic and telephonic members are now. There will be no discussions because there will be no Papers to discuss—for official reasons. There will be but three gatherings of the Institution every year: an Annual Meeting to silently receive and adopt an annual report, which will be taken as read, an Annual Dinner and an Annual Conversazione. Such is "the sad presage of its future years"!

The subsidiary applications of the electric current have not witnessed any remarkable development during 1895, but there has been healthy progress, nevertheless. The advocates of electric coal-cutting and electric welding continue to peg out their claims, but with no very startling result. Electric heating and cooking, thanks to hard experimenting and hard pushing, are coming satisfactorily to the fore. The electric furnace is finding many new industrial applications. In electro-chemistry there is much scientific activity, as witness, for instance, the abortive Börchers battery, and equally great commercial activity, more especially in the direction of the electrolytic production of caustic soda and bleach.

Patent litigation, which has been such an unpleasantly prominent episode of each electrical year, still retains this prominence, but the locus of the disturbance is no longer in this country, but in America. There, a vigorous assertion of legal rights by the owners of the Tesla polyphase patents is pending, and a similar enforcement of the law is threatened in France and Germany. In Italy the Zipernowsky-Déri-Blathy transformer patents have been upheld. In America the Thomson-Houston arc-light-dynamo-regulator patent and the Sawyer-Man glow-lamp patent have been invalidated, and the Van Depoele under-running trolley patent has been upheld. With us the threatened litigation between the E.P.S. Company and the Chloride Electrical Storage Syndicate ended in a compromise. In August Mr. Justice Stirling seconded the well-meant efforts of the Board of Trade by declaring that the term "street-box," contained in all recent Electric Lighting Orders, included excavations under the pavements intended to contain transformers, and thus, for once, the law lent a little assistance to electrical enterprise.

A year in which the Institution of Electrical Engineers has received communications such as that of Prof. Ewing on his beautiful magnetic hysteresis-meter, Dr. John Hopkinson's interesting address on the propagation of magnetism in iron, and Mr. Mark Robinson's Paper on the high-speed engine, cannot be deemed unfruitful. On the other hand, the Northern Society of Electrical Engineers continues to obtain Papers, many of which compare well with those read in Great George-street, and the newly-formed Association of Municipal Electrical Engineers, although intended mainly as a social

Digitized by Google

organisation, will doubtless drain away some more practical Papers to the loss of the parent society. With these and other still more important considerations in view, it is not altogether surprising that there should exist a widespread feeling in favour of more vigorous administration. A little more youth at the prow might result in a little more skill and energy at the helm.

As we have already remarked, there would appear to have been something in the nature of a lull in the scientific electrical world as well as in the engineering electrical world. Electromagnetic waves are becoming more and more manageable in size, and more and more analogous in their behaviour to the so-called light waves. Much good work has been done, and is being done, in investigating the influence of alternate-current waves of different shape on the efficiency of the arc, on the iron losses in transformers, &c., &c. We have already alluded to Dr. JOHN HOPKINSON'S elaborate research on the time taken by magnetism to penetrate into the interior of large iron cores, and to the ingenious device of Prof. EWING for measuring hysteresis in sheet iron. The valuable work which has been done by Mrs. AYRTON in connection with the electric arc is well known to our readers. An event of mingled scientific and practical import was the Ipswich report of the Electrical Standards Committee of the British Association on magnetic units and the interesting discussion in our columns which preceded it. The recommendations of the Committee were, as our readers may recollect, to the effect that the unit of magnetic flux should be 10^8 C.G.S. lines and should be denominated the *weber*, and that the unit of magneto-motive force should be the same as the present C.G.S. unit, and should be denominated the *gauss*.

No record of the past twelvemonth would be complete without at least some passing mention of those who have fallen out of the ranks. Four well-known telegraph men have passed away—namely, Mr. J. H. GREENER and Mr. T. FULLER in England, and Col. HOSKIÖR and Mr. ROYAL E. HOUSE, the former well known in Scandinavia, the latter in America. The band of world-famous dynamo constructors is poorer, also, by the deaths of SIGMUND SCHUCKERT and RUDOLPH EICKEMEYER. Lastly, we would call to mind the sad end of the universally-popular FRANKLIN LEONARD POPE.

But the year 1895, if it be deemed electrically noteworthy at all by those who come after us—which is doubtful—will not in all probability be remembered by any of the events we have hitherto chronicled, but rather by reason of the fact that the great Falls of Niagara were for the first time in their history seriously and scientifically converted to a utilitarian purpose in a manner which gives promise of future great developments.

SUMMARY OF ELECTRICAL EVENTS FOR 1895.

JANUARY.

Berlin-Memel telephone trunk line opened to the public, 632 miles (1st).
Liverpool Town Council decide to purchase the undertaking of the Liverpool Electric Supply Company (9th).
Presidential Address of Mr. Crompton to the Institution of Electrical Engineers (10th).
Faure "Pasted Plate" Patent No. 129 of 1881 expired (11th).
Lane-Fox Glow Lamp Patent No. 225 of 1881 expired (18th).
The threatened litigation between the E.P.S. Company and the Chloride Electrical Storage Syndicate compromised.
Belfast Municipal Electric Lighting Station started (23rd).
Hartlepool Corporation sanction the adoption of electric traction.
The City and South London Railway Company adopt the motor-car train system.
Great strike of motormen and others on the Brooklyn trolley lines.
Death of Mr. Rudolph Eickemeyer (23rd).
Deputation of the Municipal Corporations Association to the Postmaster-General to protest against the Draft Agreement (24th).
London County Council refuse to sanction the "trolley" system on the Shepherd's Bush-Acton line (29th).
Opening of the Wolverhampton Municipal Electric Lighting Station (30th).
Light Railway Conference Committee presents its report, which is adopted (31st).
Dividends declared: Anglo-American Telegraph Company, $2\frac{1}{10}$ per cent.; City and South London Railway Company, $1\frac{1}{4}$ per cent.

FEBRUARY.

Important decision by Mr. Justice Kekewich in Farmer *v.* Waterloo and City Railway Company, in which he laid down that the Company's Act did not entitle it to use the subsoil without payment (1st).
Deputation of the London County Council to the Postmaster-General to protest against the Draft Agreement and to suggest the granting of a telephone licence to the County Council (3rd).
Serious fire at the Kensington Court electric lighting station (12th).
Completion of the laying of the Cadiz-Canary Islands cable laid by the "Dacia" (13th).
Paper on "Reversible Regenerative Armatures and Short Air-Space Dynamos" read before the Institution of Electrical Engineers by Mr. W. B. Sayers (14th).
Double refraction with Hertzian waves shown by Herr K. Mack.
Opening of the Blackburn Municipal Central Station (18th).
Important experimental Paper on "The Propagation of Magnetism in Iron" read before the Institution of Electrical Engineers by Dr. John Hopkinson (21st).
Death of Mr. Royal Earl House, one of the early American telegraph pioneers and inventors of a printing telegraph (23rd).
Expiry of the Edison "electro-plated joint" Glow Lamp Patent (No. 768 of 1881) (23rd).
The Intercolonial Postal and Telegraph Conference at Hobart results in the renewing on a modified basis of the Australian cable guarantee.
Expiry of the Ayrton and Perry Electric Railway Patent No. 783 of 1881 (24th).
Dividends declared: Notting Hill Electric Lighting Company, 1 per cent.; Cambridge Electric Supply Company, $2\frac{1}{2}$ per cent.; City of London Electric Lighting Company, 5 per cent.; Chelsea Electricity Supply Company, 5 per cent.; Charing Cross and Strand Electricity Supply Corporation, $4\frac{1}{2}$ per cent.; Isle of Man Tramways and Electric Power Company, 15 per cent.; Liverpool Overhead Railway, 2 per cent.; Westminster Electric Supply Corporation, 5 per cent.; Kensington and Knightsbridge Electric Lighting Company, 5 per cent.; Telegraph Construction and Maintenance Company, 20 per cent.; Yorkshire House-to-House Company, 4 per cent.; St. James's and Pall Mall Company, $6\frac{1}{2}$ per cent.; Liverpool Electric Supply Company, $5\frac{1}{2}$ per cent.; Newcastle and District Electric Lighting Company, 6 per cent.; India Rubber, Gutta Percha and Telegraph Works, 10 per cent. (comparing with $12\frac{1}{2}$ per cent. in 1894.)

MARCH.

In consequence of a resolution moved in the House of Commons by Mr. Benn, the Postmaster-General consents to the appointment of a committee to inquire into the adequacy, or otherwise, of the telephone service (1st).
Metallic sodium discovered in the conduits of the St. Pancras Vestry; appointment of a committee composed of members of the Royal Society and Institution of Electrical Engineers to advise the Board of Trade on the matter.
Decision given by the United States Supreme Court in the Bate Refrigerator Patent case. Judgment that an American patent dates from its issue and not from the date of application. This decision involved the termination of several important electrical patents (4th).
Sunderland Municipal Electric Lighting Station opened (6th).
Completion of the Indo-Chinese land line (16th).
An important Paper, entitled "A Method of Preventing Armature Reaction," read before the American Institute of Electrical Engineers by Prof. Ryan and M. E. Thompson (20th).
Burning out of Mr. Nikola Tesla's laboratory.
First meeting of the Select Committee of the House of Commons appointed to consider the condition of the telephone service in Great Britain (22nd).
The Chemical Society confers its Faraday Medal on Lord Rayleigh in recognition of his discovery of Argon.
Zipernowsky-Déri-Blathy Transformer Patents upheld in Italy.
Paper on Railway Electric Lighting read before the Institution of Electrical Engineers by Mr. W. Langdon (28th).
Dividends declared: Birmingham Electric Supply Company, 4 per cent.; Hove Electric Lighting Company, 3 per cent.; W. T. Henley's Telegraph Works Company, 6 per cent.; Eastbourne Electric Light Company, $7\frac{1}{2}$ per cent.; British Insulated Wire Company, 7 per cent.

Digitized by Google

APRIL.

Mozambique-Majunga cable completed (1st).
Reduced cable rates to South Africa came into operation (1st).
Cable between Isle of Mull and the mainland having broken down, signals by induction were successfully transmitted.
Westinghouse and General Electric Companies of America "pool" their patents.
Prof. Elisha Gray brings out a *two*-wire telautograph.
Death of Mr. J. H. Greener (7th).
Report of the Committee appointed by the Board of Trade to inquire into the cause of the alkaline deposits in the St. Pancras conduits (10th).
Edinburgh Municipal Electric Lighting Station opened (11th).
Important Paper on "A Magnetic Tester for Measuring Hysteresis in Sheet Iron" read before the Institution of Electrical Engineers by Prof. J. A. Ewing (25th).
Opening of the Leicester Municipal Electric Lighting Station (25th).
Light Railways Bill introduced (26th).
Expiry of the Brush Current-Regulator Patent No. 1,835 of 1881 (28th).
Opening of the Chicago Elevated Electric Railway.
Dividends declared: Southampton Electric Light and Power Company, 2½ per cent.; Great Northern Telegraph Company, 8·6 per cent.; Indo-European Telegraph Company, 10 per cent.; Oriental Telephone and Electric Company, 4¼ per cent.; Oxford Electric Company, 1 per cent.; Metropolitan Electric Supply Company, 3 per cent.; Norwich Electricity Company, 3 per cent.; Eastern Extension Telegraph Company, 7 per cent.

MAY.

Treasury and London County Council agree to grant electric lighting loans for a term of 42 years, provided all renewals and repairs are paid out of revenue.
"James Forrest" lecture on "The Development of the Experimental Study of Heat Engines" delivered by Prof. W. C. Unwin (2nd).
Death of Mr. Thomas Fuller (3rd).
Paper on "The Recent Development of the Single-Acting High-Speed Engine for Central Station Work" read before the Institution of Electrical Engineers by Mr. Mark Robinson (9th).
Expiry of the Gülcher Arc Lamp Patent No. 2,038 of 1881 (10th).
Settlement of the Muirhead Duplex Patent cases; the Commercial Cable Company paying the plaintiffs a large sum of money by way of royalties, &c. (14th).
Photometric Standards Committee recommend the adoption of a 10-candle Methven-pentane standard.
Death of Lieut. Peral, of the Spanish Navy, designer of an electrically-driven submarine boat (25th).
Dividends declared: London Platino-Brazilian Telegraph Company, 1¼ per cent.; Western and Brazilian Telegraph Company, 3 per cent.; Consolidated Telephone Construction and Maintenance Company, 1½ per cent.

JUNE.

Death of Rear-Admiral Fleuriais.
Death of Col. O. V. Hoskiär (23rd).
Fire at the Sardinia-street Station of the Metropolitan Electric Supply Company (24th).
Public invited to subscribe to the Central London Railway (24th to 26th).
The Commissioners of Sewers decide to carry out a series of experiments in connection with the electric lighting of the side streets of the City (25th).
Report of the Select Committee on the Telephone Service (25th).
Dividends declared: Chatham, Rochester and District Electric Lighting Company, 2½ per cent.; Electric and General Investment Company, 20 per cent.; Telegraph Manufacturing Company, 7½ per cent.

JULY.

Niagara Electric Power Station comes into operation (1st).
Expiry of Dr. John Hopkinson's "Series-Parallel Control" Patent No. 2,980 of 1881.
Central London Railway ordered to be commenced.
Unveiling of the Ohm Statue at Munich (5th).
President and Council of the Royal Society decide to call together an International Conference in July, 1896, to discuss the question of an International Catalogue of Scientific Papers (5th).
Post Office Telephone Trunk Wires opened to the public (16th).
The whole tramway system of Budapest to be equipped electrically; in town, on the conduit system; in suburbs, on the overhead wire system.
Formation of the Amazon Telegraph Company for the purpose of laying a sub-fluvial cable network at the mouth of the Amazon.
Purchase of the business of the Liverpool Electric Supply Company by the Liverpool Corporation for the sum of £400,000.
Telegraphic communication effected with the Fastnet by means of a "discontinuous" cable (18th).
Expiry of the Maxim Glow-Lamp Patent No. 3,189 of 1881 (21st).
Dividends declared: Electrical Power Storage Company, 5 per cent.; United River Plate Telephone Company, 3 per cent.; National Telephone Company, 5 per cent.; Direct United States Cable Company, 2 per cent.; Eastern Telegraph Company, 6½ per cent.; Chili Telephone Company, 2½ per cent.; Globe Telegraph and Trust Company, 4⅛ per cent.; Edison and Swan United Electric Light Company, 5 per cent.; National Telephone Company, 5 per cent.

AUGUST.

Mr. Justice Sterling, in the action brought by the Wandsworth District Board of Works against the County of London and Brush Provincial Company, decided that the Board of Trade was entitled to extend the term "street boxes" so as to include "transformer pits" under the pavement (3rd).
Opening of the Salford Municipal Electric Light Station (7th).
Opening of the Snaefell electric tramway (16th).
Working arrangements entered into between the Westinghouse Electric and Manufacturing Company of Pittsburg and the Baldwin Locomotive Works of Philadelphia combine.
Dividends declared: Cuba Submarine Telegraph Company, 8 per cent.

SEPTEMBER.

Expiry of the Sellon "Corrugated Plate" storage battery patent, No. 3,926 of 1881 (10th).
M. M. Schneider et Cie., sole concessionaires for France of the Tesla rotary-field patents, commence infringement suits against a large number of French firms.
Meeting of the British Association at Ipswich (11th). Electrical Standards Committee recommend that the practical unit of magnetic flux be 10^8 C.G.S. lines, and be called a *weber*, and that the practical unit of magnetomotive force be the same as the C.G.S. unit, and be called a *gauss*.
An annual subsidy of $40,000 and exclusive American cable landing rights for 20 years granted by the Hawaiian Government to an American sugar planter.
Death of Herr Schuckert (16th).
Opening of the Stafford Municipal Electric Light Station (25th).
Expiry of the Swan "Carbon-joint" Glow Lamp Patent No. 4,202 of 1881 (29th).
St. Pancras Vestry announce that all future customers must be prepared to receive a 220-volt supply.
Exeter Town Council decide to purchase the local electric lighting company's undertaking.

OCTOBER.

Tunbridge Wells Municipal electric light station opened (9th).
Death of Mr. Franklin Leonard Pope (13th).
Newport (Mon.) Municipal electric light station opened (14th).
Contract signed for the laying of a new French cable from Brest to New York.
Bristol-Kingswood electric tramway opened (14th).
Leeds City Council adopt the principle of electric traction (15th).
Publication of Major Cardew's Report on the Portrush accident.
"Jandus" 200-hour carbon arc lamp brought before the public (24th).
Invalidation of the Thomson-Houston Arc Light Dynamo Regulator Patent sustained by the United States Circuit Court of Appeals at Chicago.
Dividends declared: Brazilian Submarine Telegraph Company, 7 per cent.

NOVEMBER.

Royal Medal awarded to Prof. Ewing for his investigations on magnetic induction in iron and other metals.
Paper on "Municipal Telephony" read before the Northern Society of Electrical Engineers by Mr. A. R. Bennett (11th).
United States Supreme Court of Appeal invalidate the Sawyer-Man Glow-Lamp Patent (11th).
Dinner to Mr. W. T. Ansell to celebrate his jubilee in the telegraph service (14th).
Coventry Municipal Electric Light Station opened (16th).
Deputation of Colonial representatives to Mr. Chamberlain in connection with the Pacific Cable scheme; a Joint Commission promised (19th).
Conference at the Westminster Town Hall in connection with the Board of Trade Revised Electric Lighting Regulations (19th and 20th).
Destruction of the Crompton Works by fire (22nd).
A paper on "The Use of Dust Destructors as Steam Producers for Electricity Supply Stations," read before the Northern Society of Electrical Engineers by Mr. E. Manville (25th).
Coventry Electric Tramway came into operation.

Digitized by Google

DECEMBER.

Publication of the Report of a Special Committee of Representatives of German Electricity Works on the state of the glow-lamp industry in Germany; electric light undertakers recommended to take the supplying of glow-lamps to their customers into their own hands in order to protect their own interests.

Publication of the Report of the Board of Trade expert committee on the definition of "low pressure" and cognate matters: 500 volts continuous and 250 volts alternating recommended as the limit of "low pressure"; earthing of the neutral of a three-wire system and a maximum house pressure of 250 volts also recommended for adoption (2nd).

Shrewsbury Central Station opened (10th).

Annual General Meeting of the Institution of Electrical Engineers; the question of reform raised (12th).

Van Depoele Under-Running Trolley Patent sustained in the United States.

LAMP-CONNECTION DIAGRAMS.

The diagrams given below will, we trust, render the statistics published this week in our central-station table somewhat more digestible, and at the same time serve to bring out their significance.

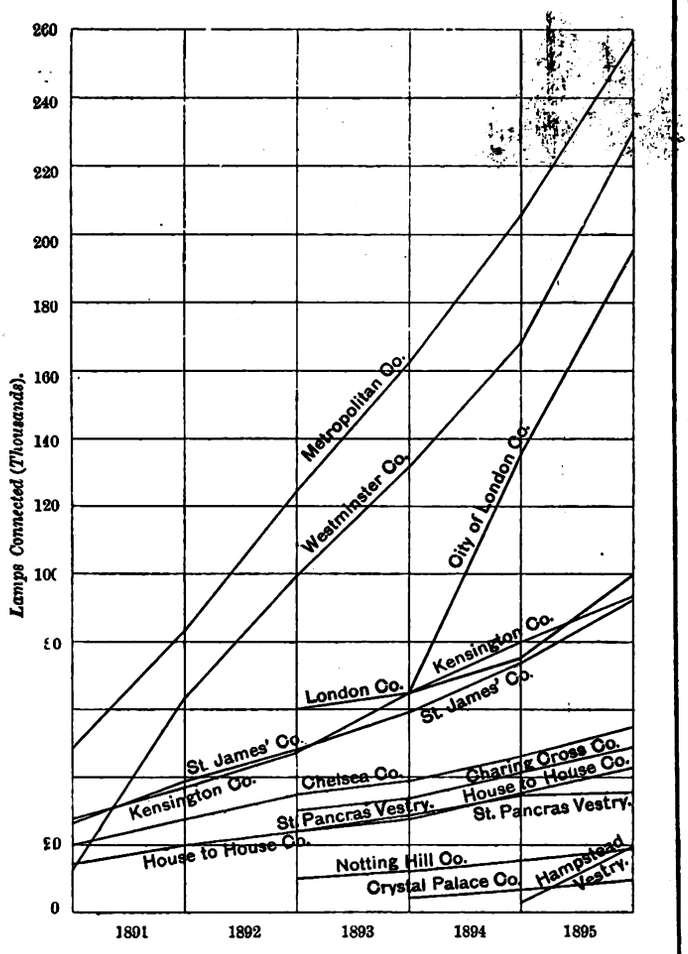

DIAGRAM 1.—Lamp Connections of the London Companies.

It will be seen from Diagram 1 that the Metropolitan Electric Supply Company still maintains its position of the premier electric supply company of London, the Westminster Electric Supply Corporation making an excellent second, and the City of London Electric Lighting Company a good third, the rest being nowhere (in the Pickwickian sense, of course). None of the curves, however, with the exception of that relating to St. Pancras, show any signs of the approach of the elastic limit. Indeed, the Metropolitan and Westminster curves look as if they were making an asymptotic approach to an infinitely great lamp connection, and the steep ascent of the City curve is positively alarming. The total lamp connection of London is now 1,178,600, as against 925,100 last year and 180,000 in 1890.

In Diagram 2 are given the lamp connections of London and the Provinces from 1890 onwards. The rapid manner in which the Provinces have caught up the Metropolis is strikingly

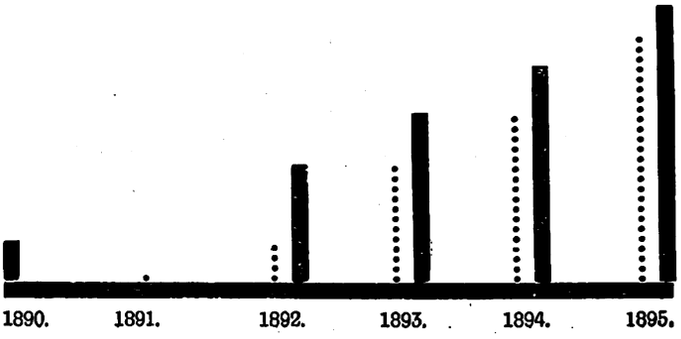

DIAGRAM 2.—Lamp Connections of London and Provinces.
London ———. Provinces .....
Scale (approx.) 1 inch = 800,000 Lamps.

shown; they now have, in round figures, 1,100,000 lamps, against London's 1,178,000. The provincial total last year was 670,000; the lamp connections of the metropolis have, therefore, only increased by 27 per cent., those in the provinces by 64 per cent.

DIAGRAM 3.—Alternate-current (.....) and Continuous-Current (———) Lamp Connections.
Scale (approx.) 1 inch = 800,000 Lamps.

In Diagram 3, the relative lamp connections of the alternate-current and of the continuous-current systems at the end of 1895 are represented. It will be observed that the alternate-current now leads the way in London.

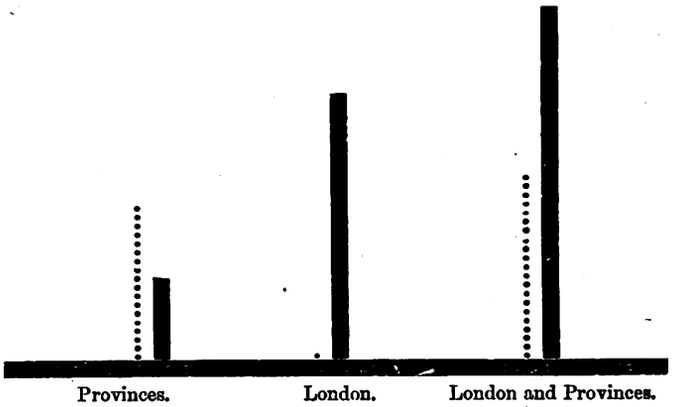

DIAGRAM 4.—Municipal (.....) and Company (———) Lamp Connections.
Scale (approx.) 1 inch = 800,000 Lamps.

In Diagram 4, the relative lamp connections of municipal and company networks at the end of last year are set out diagrammatically. Although municipal electric lighting now takes the leads well in the provinces, it is very much of a negligible quantity in London.

Digitized by Google

Below the totals are set out in tabular form :—

Table I.—*Alternate-current and Continuous-current Lamp Connections.*

—	∿	⎓	Totals.
London	614,100	564,500	1,178,600
Provinces	476,100	624,200	1,100,300
Totals	1,090,200	1,188,700	2,278,900

Table II.—*Municipal and Company Lamp Connections.*

—	Municipal.	Company.	Totals.
London	56,000	1,122,600	1,178,600
Provinces	724,400	375,900	1,100,300
Totals	780,400	1,498,500	2,278,900

SOME ELECTRICAL PATENTS EXPIRING THIS YEAR.

The following is a list of important or otherwise interesting electrical patents which, having been acquired during 1882, will, on the assumption that they have not been allowed to lapse, expire during the present year :—

Dated 1882.	No.	Name.	Subject.
Jan. 4	49	John Hopkinson	Measuring and recording quantity of electricity.
Jan. 5	55	John Perry	Apparatus used in the distribution of electrical energy.
Jan. 5	64	R. J. Gülcher	Magneto and dynamo-electric machines.
Jan. 10	129	W. H. Preece and Jabez James	Electrically lighting railway trains.
Jan. 12	178	C. E. Spagnoletti.....	Signalling upon railways.
Jan. 17	245	A. de Khotinsky	Apparatus for regulating electric currents.
Jan. 18	252	Tommasi	Electrical accumulators.
Jan. 21	319	John S. Sellon.....	Construction of secondary batteries.
Jan. 23	339	B. A. Abakanowicz...	Regulating electric lamps.
Jan. 24	346	R. E. B. Crompton...	Arc lamps.
Jan. 26	386	W. T. Henley	Cores for telegraph cables.
Jan. 31	489	G. Skrivanoff	Primary batteries.
Feb. 2	513	C. V. Boys	Electric meters.
Feb. 6	563	A. J. Jarman	Arc lamps.
Feb. 9	626	A. A. Common	Arc lamps.
Feb. 11	661	H. H. Eldred	Telephone exchange systems and apparatus.
Feb. 11	677	W. E. Langdon	Interlocking electric signalling apparatus.
Feb. 11	686, 687, 688, 689	G. M. Hopkins	Telephone call or signalling apparatus.
Feb. 15	730	C. A. Faure	Apparatus for measuring and registering electric currents.
Feb. 15	740	Solignac and Co.....	Arc lamps.
Feb. 16	758	F. J. Cheesbrough ...	Telegraph instrument.
Feb. 16	760	E. W. Siemens	Dynamo-electric machine.
Feb. 21	831	John Rapieff	Arc lamps.
Feb. 24	898	James Brockie...	Improvements in arc lamps.
Feb. 27	941	John Richardson.....	Electrically controlling the speed of engines employed for driving electric machines.
March 3	1,023	T. A. Edison	Indicating and regulating the current of electric generators.
March 6	1,079	W. Crookes	Incandescent electric lamps.
March 8	1,137	W. H. Davies and F. H. W. Higgins	Street fire alarms.
March 10	1,163	E. Weston	Arc lamp.
March 17	1,303	F. van Rysselberghe	Telegraphic and telephonic systems.
March 21	1,368	A. E. Dolbear	Electric cables.
March 25	1,412	O. E. Woodhouse and F. L. Rawson	Incandescent lamps.
March 25	1,444	R. Werdermann	Incandescent lamps.
March 27	1,464	F. de Lalande	Primary battery.
March 28	1,496	T. A. Edison	Dynamo machines.
March 29	1,516	Berthoud, Borel et Cie.	Insulation.
April 3	1,614	E. Weston	Dynamo armatures.
April 3	1,619	H. Maxim	Carbons for incandescent lamps.
April 5	1,642	W. H. Akester.....	Incandescent lamps.
April 5	1,647	St. G. Lane-Fox	Incandescent lamps.
April 13	1,769	C. A. Faure	Secondary batteries.
April 17	1,830	Fleeming Jenkin.....	Telpherage.
April 20	1,895	A. Cruto	Incandescent lamps.
April 20	1,896	A. C. Brown and H. A. C. Saunders.	Telephonic and telegraphic signalling.
May 2	2,072	T. A. Edison	Arc lamps.
May 3	2,092	C. Lever	Arc lamps.
May 11	2,237	A. d'Arsonval	Microphonic transmitters.
May 18	2,340	Baron Elphinstone and C. W. Vincent.	Dynamo electric machines.
May 27	2,526	J. J. Wood	Dynamo.
May 27	2,531	J. J. Wood	Dynamo armatures.
May 31	2,578	S. P. Thompson	Telephone instruments.
June 3	2,618	R. E. B. Crompton...	Dynamo.
June 5	2,642	W. E. Ayrton and J. Perry.	Electric meter.
June 8	2,694	E. Weston	Dynamo armatures.
June 9	2,712	F. Krizik and L. Piette.	Arc lamp (Pilsen).
June 14	2,807	L. Epstein	Secondary batteries.
June 15	2,818	J. S. Sellon	Secondary batteries.
June 15	2,830	W. E. Ayrton and J. Perry.	Electric motors.
June 17	2,871	J. E. H. Gordon	Dynamo. [lamps.
June 19	2,898	J. W. Swan	Manufacture of incandescent
July 6	3,204	E. Thomson.....	Dynamo machinery, &c.
July 10	3,271	T. A. Edison	Electric meters.
July 11	3,296	G. Planté.....	Preparing sheet lead plates for secondary batteries.
July 17	3,380	W. E. Ayrton and J. Perry.	Electric haulage.
July 18	3,419	S. Z. de Ferranti and A. Thompson.	Dynamo alternator.
July 27	3,576	J. Hopkinson	Distributing electricity (3-wire system).
Aug. 4	3,710	P. B. Elwell and T. Parker.	Electric lighting machinery and apparatus.
Aug. 5	3,752	T. A. Edison	Transmitting electricity.
Aug. 5	3,755	T. A. Edison	Electric meters.
Aug. 5	3,756	T. A. Edison	Dynamo.
Aug. 8	3,770	L. Epstein	Preparation of lead for secondary batteries.
Aug. 9	3,803	S. P. Thompson	Telephonic apparatus.
Aug. 17	3,950	S. Z. Ferranti and A. Thompson.	Dynamos.
Aug. 18	3,955	T. A. Edison	Incandescing glow lamp filaments.
Sept. 1	4,178	D. G. FitzGerald and T. J. Jones.	Secondary batteries.
Sept. 9	4,303	E. Frankland	Secondary batteries.
*Sept. 13	4,362	L. Gaulard and J. D. Gibbs.	"A new system of distributing electricity for the production of light and power."
Sept. 14	4,376	M. Deprez	Dynamos.
Sept. 15	4,390	J. W. Swan and C. Swan.	Incandescent lamp holders.
Sept. 16	4,421	A. C. Brown and H. A. C. Saunders.	Telegraphic and telephonic apparatus.
Sept. 19	4,460	G. G. Skrivanow.....	Primary batteries.
Sept. 23	4,536	C. Zipernowsky and M. Deri.	Dynamos.
Sept. 23	4,548	F. Jenkin	Telpherage.
Oct. 4	4,718	J. Hopkinson	Electric traction.
Oct. 10	4,810	R. E. B. Crompton and G. Kapp	Dynamos.
Oct. 14	4,884	T. A. Edison	Electrical distribution (feeder system).
Oct. 20	5,001	G. L. Anders	Telephonic apparatus.
Nov. 15	5,438	R. E. B. Crompton ...	Conduction and distribution of electric currents.
Nov. 24	5,594	B. Abdank-Abakanowicz & C. Roosevelt	Dynamos.
Nov. 29	5,669	J. Blyth	Ammeter.
Nov. 29	5,673	R. S. Waring	Electric cables.
Dec. 8	5,870	A. E. Dolbear	Telephonic apparatus.
Dec. 15	6,002	G. Trouvé.....	Primary battery and system of interior lighting.
Dec. 20	6,075	A. Bernstein.....	Incandescent lamps.
Dec. 27	6,185	La Société Solignac...	Arc lamp.
Dec. 28	6,193	T. A. Edison.....	Incandescing lamp filaments.
Dec. 28	6,199	T. A. Edison.....	System of elec rical distribution.

* Revoked July, 1888.

THE ELECTRIC RAILWAYS AND TRAMWAYS OF THE UNITED KINGDOM.

Place.	Length.	System.	Worked by.
In Operation :—	Miles.		
Bessbrook—Newry ..	3½	Third Rail (Dr. E. Hopkinson)	Bessbrook and Newry Tramway Company.
Birmingham	3	Accumulator Cars	Birmingham Central Tramways Company.
Blackpool	3	Holroyd - Smith's Conduit	Blackpool Corporation
Brighton.....	1	Third Rail (Volk)	Mr. Magnus Volk.
Bristol—Kingswood	4¼	Side Trolley	Bristol Tramways and Carriage Company.
Carstairs.....	1¼	Two Side Bars (Anderson-Munro)	Mr. J. Monteith, of Carstairs (Private).
London—			
City and South London Railway (King William - street—Stockwell)	3½	Third Rail (Dr. E. Hopkinson)	City and South London Railway Company
Coventry	5¾	Overhead Trolley.	Coventry Electric Tramways (Limited)
Douglas—Laxey (I. of Man)	7	Under-running "Bar" (Dr. E. Hopkinson)	Isle of Man Tramways and Electric Power Company.
Douglas (I. of Man)..	2½	Overhead Trolley.	DouglasSouthernElectric Tramways (Ltd).
Guernsey	2¾	Overhead (Siemens)	Guernsey Railway Company
Leeds (Roundhay Park Line)	3¾	Thomson-Houston Overhead Trolley	Thomson - Houston International Electric Company.
Liverpool Overhead Railway	6¼	Third Rail	Liverpool Overhead Railway Company.
Portrush — Giant's Causeway	8	Third Rail (Siemens)	Giant's Causeway Electric Tramway Co.
Ryde	¾	Third Rail (Siemens)	Ryde Pier Company.
Snaefell Mountain Railway	4¾	Overhead underrunning Bar (Dr. E. Hopkinson)	Snaefell Mountain Railway Association.
Southend Pier	1¼	Third Rail(Crompton)	Southend Corporation
Walsall, Wednesbury, Bloxwich, and Darlaston	8	Overhead Side Trolley	Electric Construction Company.
In Progress :—			
Brighton — Rottingdean	3	Overhead Trolley	Brighton and Rottingdean Seashore Railway Company.
London—			
Central London Railway (City and Shepherd's Bush)	6½	...	Central London Railway Company.
Waterloo—City.....	1½	...	South-Western Railway Company.
Dublin—Dalkey ...	8	Overhead Trolley.	Dublin Southern District Tramways Company.
Hartlepool	2½	Overhead Trolley.	Electric Construction Company.
Projected :—			
Birmingham (Nechells Line)	3	Side Trolley	Birmingham Central Tramways Company.
Blackpool — Fleetwood	...	Overhead Trolley.	...
Blackpool—Lytham.	...	...	Blackpool—St. Annes and Lytham Tramways Company
Bray—Bray Head ...	...	Overhead Trolley.	...
Colwyn Bay-Conway	10	Side Trolley	Conway-Llandudno & Colwyn Bay Tramway Company.
Derby—Ashbourne..	12	Side Trolley	Derby and Ashbourne Tramways Company.
Dover	..	...	Dover Corporation.
Dublin.....	32	...	Dublin United Tramways Company, and Dublin Southern Tramways Company.
Dublin	23	...	Dublin Southern District Tramways Company
Halifax	8	Overhead Trolley. (Holroyd-Smith.)	The Halifax & District Tramways Company.
Kidderminster—Stourport	4¾	Side Trolley	Kidderminster and Stourport Electric Tramway Company.
Leeds	...	Overhead Trolley.	Leeds Corporation.
Liverp'l & Birkenhead	4½	...	Mersey Railway Co.
Llandudno — Great Ormes Head	7	...	Manchester Edison-Swan Company.
London—			
City and S. London Rail. Extensions—			
Clapham	1	Third Rail (Dr. E. Hopkinson)	City & South London Railway Company.
Islington	2¾		
Finsbury Park & City	3¼	...	...
Finsbury — Walthamstow	3½	...	...
Hampstead, St. Pancras, & Charing-cross	5¼	...	...
Waterloo-Baker-st.	3	...	...
North Staffordshire..	...	...	North Staffordshire Tramways Company.
Portsmouth	...	...	Provincial Tramways Company.
Sheffield	...	...	London & Provincial TramwaysSyndicate.
Swansea	...	...	Swansea Tramways Company.

ELECTRIC LIGHTING NOTICES.

(SESSION 1896.)

The eliminating effect of the £50 cheque which has to be deposited with the Board of Trade by December 21st, has not been very pronounced this year, only three concerns having dropped out from the list published by us on p. 196 of our issue of December 6th. This time last year there were in all 29 applications for electric lighting powers; this year the total is 38, no less than 25 notices originating from Local Authorities.

THE METROPOLIS.

District.	Names of Applicants.
Parish of St. Mary, Newington, S.E.....	Vestry.
Parish of St. Mary, Battersea, S.W.	Vestry.
District of the St. Saviour's District Board of Works, Parishes of St. Mary (Newington), St. Mary (Lambeth), St. Giles (Camberwell), and St. Mary (Battersea), London	County of London and Brush Provincial Electric Lighting Company (Limited).

THE PROVINCES.

Allerton, Childwall and Garston (Lancs.)	Liverpool District Lighting Company (Limited).
Ambleside	Windermere and District Electricity Supply Company (Limited).
Ashton-on-Mersey	Altrincham Electric Supply (Limited).
Bath	Corporation.
Bath	City of Bath Electric Lighting and Engineering Company (Limited). [Extension of area.]
Bray	Township Commissioners.
Colwyn Bay and Colwyn	Urban District Council.
Cork	Corporation.
Cowes (Isle of Wight) ...	Urban District Council.
Devonport	Corporation.
Folkestone	Corporation.
Gloucester	Corporation.
Godalming	Corporation.
Great Berkhamsted and Northchurch	Bedford Electric Light Company (Limited).
Great Crosby & Waterloo, with Seaforth, ...	Liverpool District Lighting Company (Limited)
Huddersfield	Corporation. [Extension of area.]
Ipswich	County of London and Brush Provincial Electric Lighting Company (Limited).
Keswick	Urban District Council.
Ditto	Keswick Electric Light Company (Limited).
Kettering	Urban District Council.
King's Lynn	Corporation.
Kingstown	Township Commissioners.
Liverpool	Corporation.
Manchester.....	Corporation. [Extension of area.]
Margate	Corporation.
Merthyr Tydfil.....	J. C. Howell (Limited).
Middleton	Corporation.
Newmarket.....	Newmarket Electric Light Company (Limited).
Pembroke (Ireland)	Township Commissioners.
Prescot	British Insulated Wire Company.
Queenstown	Township Commissioners.
Rathmines and Rathgar (Dublin).....	Improvement Commissioners.
St. George, Kingswood, Stapleton and Warmley (Bristol)	Great Western Electric Light and Power Company, (Limited).
Sale	Urban District Council.
Wells	Corporation.

THE RELATION BETWEEN THE ATOM AND THE CHARGE OF ELECTRICITY CARRIED BY IT.*

BY J. J. THOMSON, M.A., F.R.S.

In the electrolysis of solutions, the persistency of the sign of the electric charge carried by an ion is almost as marked a feature as the constancy of the magnitude of the charge. Thus the hydrogen ion always carries a positive charge, the chlorine ion a negative one. In the electrolysis of gases, however, the sign of the charges carried by the atoms of different elements is much more variable: here an atom of hydrogen does not always carry a positive charge, nor an atom of chlorine always a negative one; each of these atoms sometimes carries a negative charge, sometimes a positive one. But though in the gaseous state the atoms do not restrict themselves to charges of one sign, there are many phenomena which prove that even in this state the atoms of the different elements behave differently with respect to positive and negative charges. v. Helmholtz explained this behaviour of the elements by supposing that there is a specific attraction between the atom and its charge; that the zinc atom, for example, attracts a positive charge more powerfully than it does a negative one, while an atom of chlorine, on the other hand, attracts a negative charge more powerfully than it does a positive one.

The connection between ordinary matter and the electrical charges on the atom is evidently a matter of fundamental importance, and one which must be closely related to a good many of the most important chemical as well as electrical phenomena. In fact a complete explanation of this connection would probably go a long way towards establishing a theory of the constitution of matter as well as of the mechanism of the electric field. It seems therefore to be of interest to look on this question from as many points of view as possible, and to consider the consequences which might be expected to follow from any method of explaining, or rather illustrating, the preference which some elements show for one kind of electricity rather than the other.

The following method of regarding the electric field seems to indicate that this effect may be illustrated by simple dynamical appliances. The charges on the atoms are regarded as the ends of Faraday tubes (*see* J. J. Thomson, "Recent Researches in Electricity and Magnetism," p. 2): each unit of positive charge is the origin, each unit of negative charge the termiuation of such a tube. The magnitude of the unit charge is here taken equal to the charge carried by a monovalent ion. When these tubes spread into the medium they give rise to Maxwell's *Electric Displacement*, and the motion of the tubes through the medium produces a magnetic field.

Now suppose that the medium forming these tubes possesses rotatory motion: we may imagine, for example, that the tubes are bundles of vortex filaments, the axis of rotation being parallel to the axis of the tube. The total amount of vorticity which starts from any solid totally immersed in a liquid is zero; to satisfy this condition, we may suppose that there is slipping between the walls of the bundle of vortex filaments and the surrounding liquid, or, what amounts to the same thing, that there is on the surface of the bundle a film of negative vorticity whose strength is equal and opposite to the positive vorticity of the core. To fix our ideas, let us suppose that the rotation in the core is related to the direction of the axis of the tube (the line running from the origin to the end of the tube) like rotation and translation in a right-handed screw.

Now let us consider the atoms on which these tubes end. Let us suppose that these atoms have a structure possessing similar properties to those which the atoms would possess if they contained a number of gyrostats all spinning in one way round the outwardly drawn normals to their surface. Then one of these atoms will be differently affected by a Faraday tube, and will possess different amounts of energy according as the tube begins or ends on its surface. For if, when the tube starts from the atom, the rotation in the core of the tube is in the same direction as the rotation of the gyrostats, then when a tube ends on the atom the rotation in the tube will be in the opposite direction to that of the gyrostats. Thus in the first case the tube will tend to twist a gyrostat in the same direction as that in which it is already spinning, while in the second case it will tend to twist it in the opposite direction. Now if we try to rotate a gyroscopic system, its behaviour when we try to make it rotate in the direction in which the gyroscopes are spinning is quite different from its behaviour when we try to spin it in the opposite direction.

Thus let Fig. 1 represent a balanced gyrostat which can rotate as a whole about the vertical axis A B; the heavy flywheel C D is supported so that its axis can move freely in a vertical plane. Let this flywheel be in rapid rotation with its axis vertical; the framework of the gyrostat will not tend to rotate. Now if we set the framework rotating about the vertical axis, the behaviour of the system, if we make the framework rotate in the direction in which the flywheel is spinning, will be very different from its behaviour when we make the framework rotate in the opposite direction. If the framework rotates in the same direction as the flywheel, the axis of the wheel remains vertical, and the whole system goes on rotating quietly until stopped by friction. If, however, we attempt to set the framework rotating in the opposite direction to the flywheel, the axis of the wheel begins to wobble about, the disturbance gets more violent until finally the flywheel topples right over; then the flywheel is rotating in the same direction as the framework, and the rotation goes smoothly on. If the axis of the flywheel were held in its original position by springs, then in the first case these springs would not be stretched; but in the second case they would, and the axis of the flywheel would take up a position inclined to the vertical, the angle it made with the vertical depending on the stiffness of the springs and the moment of momentum of the flywheel. Thus in the second case the attempt to make the framework of the gyrostat rotate would be accompanied by the storing up of potential energy in the system due to the stretching of the springs, while there would be no such storage of potential energy in the first case.

Suppose, now, that an atom of hydrogen possesses a structure analogous to this gyroscopic system with springs, the gyrostats rotating in the same direction as the fluid in a Faraday tube *leaving* the atom. Then, since a charge of negative electricity on the atom implies the *incidence* of a tube on the atom, when the hydrogen atom is charged negatively the rotation in the tube connected with the atom is in the opposite direction to that of its gyrostats. The negative charge will thus cause an increase in the potential energy of the atom, whereas a positive charge when the rotation in the tube is in the same direction as that of the gyrostats does not cause any such increase. Thus the internal potential energy of the

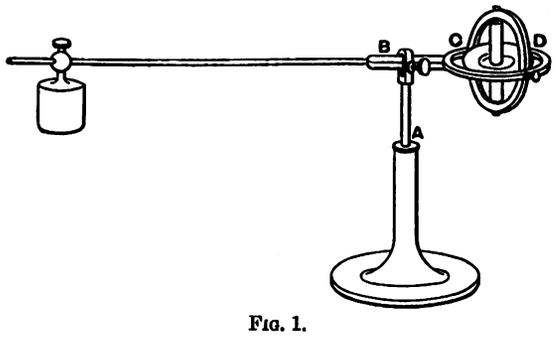

FIG. 1.

hydrogen atom will, *cæteris paribus*, be greater when it has a negative charge than when it has a positive one. In the case of a strongly electro-negative element such as chlorine, we suppose that the gyrostats in the atom are rotating in the opposite direction to those in the hydrogen atom, *i.e.* that in the chlorine atom the rotation in the gyrostats is in the *opposite* direction to that of the liquid in a Faraday tube *leaving* the atom: thus the chlorine atom will, *cæteris paribus*, have more internal potential energy when charged with positive electricity than it has when charged with negative.

The existence of the property conferred by these gyrostats would call into play forces between two charged atoms placed very close together, in addition to those given by the ordinary laws of electrostatics; it would make, for example, the attraction between a negatively charged hydrogen atom and a positively charged chlorine one less than that between a positive hydrogen atom and a negative chlorine one at the same distance apart. For imagine, in the first case, the atoms to approach a little closer together, then, besides the diminution in the potential energy due to the ordinary electric forces between the atoms, there will be an *increase* in the potential energy from the increase in the effect on the gyrostats due to the rotation in the Faraday tubes; while in the second case, when the hydrogen is positive and the chlorine negative, this increase will not take place. Thus the diminution in the potential energy due to a given diminution in the distance between the atoms is less in the first case than in the second, and consequently the attraction between them is smaller in the first case than in the second. If we could reach a place where, as the distance between the atoms diminished, the increase in the potential energy due to the effect of the gyrostats was numerically greater than the diminution in the potential energy due to the electrostatic attraction, then the oppositely-charged atoms would repel instead of attracting each other.

Hydro-dynamical Illustration.

The following illustration also indicates that the force between two electric charges may be modified by the electro-chemical properties of the atoms carrying the charges.

In a cylindrical column of rotating fluid the pressure increases with the distance from the axis of rotation, so that the average

* Abstract from the *Phil. Mag.*, Vol. XL., December, 1895.

Digitized by Google

pressure over a cross-section of the cylinder is less than the pressure at the surface of the cylinder. When a solid is immersed in a liquid where the pressure is uniform, the pressures of the liquid on the solid form a system of forces in equilibrium. Now suppose that a column of the liquid abutting on the solid acquires rotation, the pressure on the part of the solid in contact with the column will be less than the pressure outside, the pressures on the solid will no longer be in equilibrium. The defect in pressure over the cross-section of the column will give rise to a tension acting on the solid. This tension is equal to the excess of the pressure over the cross-section when the pressure is uniform and equal to that at the surface of the cylinder, over that actually exerted over the area by the rotating liquid. If the rotating column is a cylinder containing a number of vortex filaments mixed up with irrotationally moving liquid, the pressure over a cross-section of the cylinder will depend upon the distribution of the vortex filaments in the cylinder. Let the cylinder be a right circular one. Let v be the velocity, and p the pressure at a distance r from it axis, ρ the density of the liquid; then we have

$$\rho \frac{v^2}{r} = \frac{dp}{dr}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The pressure over the cross-section of the cylinder is equal to

$$\int_0^b 2\pi r p \, dr,$$

where b is the radius of the cylinder. Integrating this by parts, we find that the pressure Π over the cross-section is given by the equation

$$\Pi = P\pi b^2 - \int_0^b \pi r^2 \frac{dp}{dr} dr$$

$$= P\pi b^2 - \int_0^b \tfrac{1}{2}\rho v^2 2\pi r \, dr \quad . \quad . \quad . \quad . \quad (2)$$

by equation (1); P is the pressure at the surface of the cylinder.

The tension Δ exerted by the cylinder on the solid is given by the equation

$$\Delta = P\pi b^2 - \Pi$$

$$= \int_0 \tfrac{1}{2}\rho v^2 2\pi r \, dr \, . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$= \text{kinetic energy per unit length of the cylinder.} \quad (4)$$

Since $2\pi r v$ = vorticity inside a circle of radius r, we can, if we know the distribution of vorticity, easily calculate by means of equation (3) the value of Δ.

Let us suppose that if all the vortex filaments were collected round the axis to the exclusion of the irrotationally moving liquid, they would occupy a cylinder of radius a. Let ζ be the rotation in the vortex filament, and let

$$\int_0^b 2\pi r \zeta \, dr = m.$$

Then we find that when the vortex filaments are as close to the axis of the cylinder as possible,

$$\Delta = \frac{\rho m^2}{16\pi} + \frac{\rho m^2}{4\pi} \log \frac{b}{a}.$$

When the vorticity is uniformly distributed over the cross-section of the cylinder,

$$\Delta = \frac{\rho m^2}{16\pi}.$$

When the vorticity is all as near to the surface of the cylinder as possible,

$$\Delta = \frac{\rho m^2}{16\pi}\left\{1 - 2\frac{(b^2-a^2)}{a^2}\left(1 - \frac{(b^2-a^2)}{a^2}\log\frac{b^2}{b^2-a^2}\right)\right\}.$$

We may expand the right-hand side of the last equation, and get

$$\Delta = \frac{\rho m^2}{8\pi}\left\{\frac{1}{3}\frac{a^2}{b^2-a^2} - \frac{1}{4}\frac{a^4}{(b^2-a^2)^2} + \frac{1}{5}\frac{a^6}{(b^2-a^2)^3} - \ldots\right\},$$

so that when a is small compared with b,

$$\Delta = \frac{\rho m^2 a^2}{24\pi b^2}.$$

In this case the tension in the cylinder is very small compared with its value in the two previous cases: the value of Δ in the first case is greater than that in the second; the more the vortex filaments are concentrated at the axis the greater will be the value of Δ. Now let us suppose that a Faraday tube contains a given amount of vorticity distributed among irrotationally moving liquid; the axes of the vortex filaments being parallel to the axis of the tube. The moment of momentum of the fluid in the tube about its axis will depend upon the distribution of vorticity in the tube: the more the vorticity is concentrated near the axis of the tube the greater will be the moment of the momentum. Now suppose we apply a couple to the Faraday tube, the couple acting in such a direction as to increase the moment of momentum; this couple will cause the vortex filaments to concentrate more at the axis of the tube, and will consequently increase the tension in the tube. If, however, the couple on the Faraday tube acts in the opposite direction to the moment of momentum of the fluid in the tube, the action of the couple will cause the vortex filaments to spread out and get nearer the boundary of the tube: this will diminish the value of Δ, and consequently diminish the tension in the tube. If we suppose that the solid on which the tube abuts is an atom containing gyrostats, then when the gyrostats are rotating in the same direction as the fluid in the tube, we may regard the action between the gyrostats and the tube as equivalent to a couple tending to increase the moment of momentum of the fluid in the tube, and thus to increase the pull exerted by the tube on the atom. When, however, the rotation of the gyrostats is in the opposite direction to that of the fluid in the tube, the action between the atom and the tube will be equivalent to a couple tending to diminish the moment of momentum of the fluid in the tube, and thus to diminish the pull exerted by the tube on the atom. Thus if, as before, we suppose that the gyrostats in the hydrogen atom are rotating in the same direction as the fluid in the Faraday tube of which it is the origin when it carries a positive charge, whereas the gyrostats in the chlorine atom are rotating in the same direction as the fluid in the Faraday tube of which it is the termination when it carries a negative charge, we see that the attraction between a positively charged hydrogen atom and a negatively charged chlorine one will be greater than that between a negative hydrogen and a positive chlorine atom separated by the same distance.

The object of these illustrations is to call attention to the point that when charged atoms are close together, there may be forces partly electrical, partly chemical, in their origin in addition to those expressed by the ordinary laws of electrostatics.

There are one or two points in connection with the theory of the electric field which can be illustrated by the conception of a Faraday tube as a bundle of vortex filaments, which, though not connected with the main object of this Paper, may be briefly pointed out.

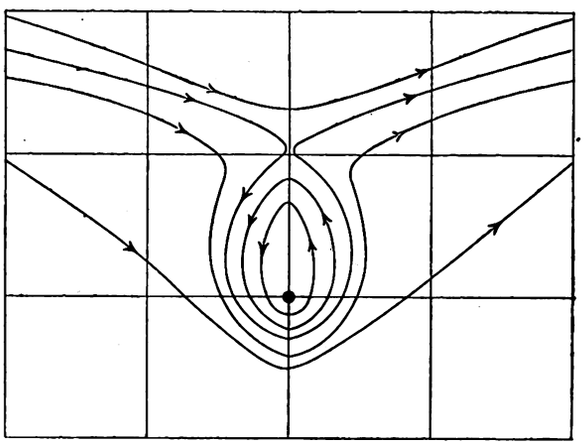

FIG. 2.

The first of these arises from equation (4), which indicates that the tension exerted by a vortex column is equal to the kinetic energy of the fluid in unit length of the column. Now we know that the forces on a charged body in the electric field are such as would be produced if there were a tension along the lines of force equal per unit area to the electrostatic energy in unit volume of the field. If we suppose the tension to be exerted by the Faraday tubes and the energy to reside in these tubes, this is equivalent to saying that the tension exerted by each of these tubes is equal to the energy in unit length of the tube. This exactly coincides with the result indicated by equation (4), if we suppose that the Faraday tubes are bundles of vortex filaments.

The other point is in connection with the view that magnetic force is due to the movement of the Faraday tubes: the magnetic force being at right angles to the direction of the Faraday tubes, and also to the direction in which they are moving, the magnitude of the force varying as the product of the "polarisation" and the velocity of the tubes at right angles to their direction (*see* "Recent Researches in Electricity and Magnetism," by J. J. Thomson, p. 8). On this view the energy per unit volume in the magnetic field when the tubes are moving at right angles to themselves is (*see* "Recent Researches," p. 9)

$$\frac{\mu}{8\pi} P^2 V^2,$$

where μ is the magnetic permeability, P the polarisation, and V the translatory velocity of the tubes. This expression would represent the kinetic energy due to the translatory motion of the tubes if the expression for the effective mass of the tubes contained a term proportional to the square of the "polarisation." Now, if we have a vortex column moving about in a fluid which is subject

Digitized by Google

to other disturbances, the following considerations would seem to show that the expression for its effective mass would contain a term proportional to the square of the vorticity in the vortex column.

The lines of flow when the vortex column is stationary in a liquid moving so that at an infinite distance its velocity is uniform and horizontal are represented in Fig. 2.

We see that some of these lines of flow in the neighbourhood of the column are closed curves; now the liquid inside any one of these curves will always remain in the neighbourhood of the column, and if the column is moved will move with it; thus the effective mass of the column will be that of the column plus that of the liquid enclosed by the largest of the closed lines of flow. The linear dimensions of the curve are proportional to m/u, where u is the velocity of the fluid at an infinite distance from the column, and m the strength of the vortex; (the equation to the bounding line of flow is easily seen to be $r=\frac{m}{u}e^{-\frac{uy}{m}}$), thus the area enclosed by the line of flow, and consequently the mass of fluid inside a cylinder of which it is the cross-section, is proportional to m^2/u^2; thus, as the effective mass is increased by this mass of fluid, the expression for the effective mass of the vortex column will contain a term proportional to the square of the vorticity. Hence, if we regard a Faraday tube as a bundle of vortex filaments, we can by this analogy see that its effective inertia might involve a term proportional to the square of the polarisation.

Relation of the preceding Analogies to the Electro-chemical Properties of the Atoms.

To return, however, to the relation between the electric charge and the electro-chemical properties of the element whose atom carries the charge. Fig. 1 suggests that when an atom is charged with electricity it acquires a certain amount of potential energy depending upon the sign of the charge and also upon the kind of atom carrying the charge. Let us suppose that when an atom of an element A carries unit charge of positive electricity, its potential energy, in consequence of the connection between the internal motion of the atom and the motion of the fluid in the Faraday tube, is greater by σ_A than when it has no charge, while when the atom has the unit negative charge its potential energy is less by σ_A than that of the uncharged atom. The quantity σ depends upon the nature of the atom; in "Recent Researches in Electricity and Magnetism," p. 64, it is called the Volta potential of the substance, since the difference of potential between two metals A and B when placed in contact can be proved to be equal to $\sigma_A - \sigma_B$.

If the substance A has a charge Q of positive electricity, then in the expression for its potential energy there will be the term $\sigma_A Q$. If we consider this term alone, then if σ_A is positive an increase in the positive charge will involve an increase in the potential energy, while an increase in the negative charge would diminish the potential energy; if σ_A is negative the converse is true. Now a dynamical system behaves so as to facilitate any change which causes a diminution in the potential energy. Thus those substances for which σ is negative will tend to acquire a charge of positive electricity, while those for which σ is positive will tend to get a charge of negative electricity. Thus the existence of the property expressed by the coefficient σ would produce the same effect as von Helmholtz's specific attraction of the elements for the two electricities.

Suppose, for example, that we have two metals A and B in contact, and that σ_A, σ_B are the values of the Volta coefficients for A and B respectively; let σ_A be greater than σ_B. Then if A acquires a negative charge equal to $-Q$, and B a positive charge equal to Q, the potential energy of the two metals will be diminished by $(\sigma_A - \sigma_B)Q$. If this were the only source of potential energy, the transference of positive electricity from A to B, and of negative from B to A, would go on indefinitely, as each transference would involve a diminution in the potential energy. The separation of the electricities will, however, produce an electric field the potential energy due to which will increase as Q increases, so that the diminution in energy due to the Volta effect will be accompanied by an increase in the energy due to the electrostatic field. Let us suppose, for example, that the two metals form the plates of a condenser whose capacity is C, then when A has a charge $-Q$ and B a charge $+Q$, the energy in the electrostatic field is equal to

$$\frac{1}{2}\frac{Q^2}{C},$$

while the energy due to the Volta effect is

$$-(\sigma_A - \sigma_B)Q.$$

The flow of negative electricity into A and of positive into B will go on until the increment in the energy of the electrostatic field due to an increase δQ in the charge on B is equal to the decrement of the energy due to the Volta effect produced by the same displacement of electricity.

Since the total energy is

$$\frac{1}{2}\frac{Q^2}{C} - (\sigma_A - \sigma_B)Q,$$

the increment when Q is increased by δQ is equal to

$$\delta Q\left\{\frac{Q}{C} - (\sigma_A - \sigma_B)\right\};$$

or, if V is the difference of potential between A and B, the increment of the potential energy is equal to

$$\delta Q\{V - (\sigma_A - \sigma_B)\}.$$

Thus, so long as V is less than $\sigma_A - \sigma_B$, an increase in Q will be accompanied by a decrease in the potential energy, so that Q will tend to increase; while, on the other hand, when V is greater than $\sigma_A - \sigma_B$, an increase in Q will be accompanied by an increase in the potential energy, so that Q will tend to diminish: there will be equilibrium when $V = \sigma_A - \sigma_B$.

We see from this that if an atom of A has a unit negative charge, an atom of B a unit positive one, these atoms will retain their respective charges even though connected by a conductor, unless the potential of B exceeds that of A by more than $\sigma_A - \sigma_B$. If, on the other hand, A had a positive charge, B a negative one, they would, if connected by a conductor, interchange their charges unless the potential of B exceeded that of A by more than $\sigma_A - \sigma_B$.

Thus, assuming that σ is positive for chlorine and negative for hydrogen, an atom of hydrogen could retain a positive charge, and an atom of chlorine a negative one, even though the two were immersed in a conductor, provided the potential of the hydrogen atom did not exceed that of the chlorine atom by more than a certain limit; whereas if the hydrogen were negatively electrified and the chlorine positively, they would, if immersed in a conductor, interchange their charges unless the potential of the hydrogen atom exceeded that of the chlorine by the same limit as before.

Chemical Combination.

Thus, if we have a number of hydrogen atoms and an equal number of chlorine atoms immersed in a conductor, and if initially half of both the hydrogen and chlorine atoms were positively and half negatively electrified, interchange of charges between the atoms would go on until all the hydrogen atoms were positively and all the chlorine atoms negatively electrified.

For this interchange of charges to go on, however, it would seem necessary that a negatively electrified hydrogen atom and a positively electrified chlorine one should be connected by a conducting

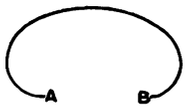

FIG. 3.

circuit. From the mechanical illustrations previously given, it seems unlikely that the atoms would interchange their charges by coming into contact, the positive charge passing from the chlorine to the hydrogen atom and *vice versâ*. From these illustrations we should rather expect that if a negative hydrogen atom came very near to a positive chlorine one, the two, if alone in the field, would tend to repel rather than to attract each other, the Faraday tube connecting the atoms ceasing to be straight, and bulging out into the surrounding medium somewhat in the manner shown in Fig. 3.

If in addition to the two atoms there were other charged bodies producing a very intense field tending to push the hydrogen and chlorine atoms together, then the interchange of their charges might take place by the ends of the Faraday tube gliding from one atom to the other after these atoms had been forced into contact by the external field. There are indications that the external field would have to be such as to produce a potential difference of a large number of volts between the two atoms before this method of exchanging their charges took place. In the absence of this potential difference, the atoms would not exchange their charges unless the medium into which the Faraday tube spread contained some conductor along which the ends of the Faraday tube could glide from one atom to the other. The necessity for this conducting circuit is perhaps one of the reasons why the presence of a third substance seems necessary for the continuance of many chemical reactions. How much a third substance able to act as a conductor could facilitate chemical combination may be seen from the following example. Suppose we have a mixture of hydrogen and chlorine molecules, and that by some external cause we split up these molecules into atoms; half of the hydrogen atoms produced by the dissociation of the hydrogen molecules will be positively electrified, while the other half will be negatively electrified; the same will also be true of the chlorine atoms. This condition will be permanent if the negative hydrogen atoms have no opportunities of interchanging their charges with the positive chlorine atoms, and a positive hydrogen atom would thus not be limited to combining with a negative chlorine one to form a molecule of hydrochloric acid, but might instead combine with a negative hydrogen atom to form a hydrogen molecule. If, however, conducting circuits, able to connect atom with atom, were present,

Digitized by Google

the circumstances would be much more favourable to the formation of hydrochloric acid. For if the conducting circuit stretched from a positive hydrogen atom to a negative chlorine one, these atoms would retain their charges; whereas when the circuits stretched from a negatively electrified hydrogen atom to a positively electrified chlorine one, the atoms would interchange their charges. Thus the effect of these conducting circuits would be to cause all the hydrogen atoms to be positively electrified, and all the chloride ones negatively; this would of course increase the tendency for the hydrogen and chlorine to combine.

In the preceding case we have supposed the molecules to be already split up into atoms; when, however, we consider the case of a mixture of molecules not already decomposed, we see that something more than the stretching of a conductor from one atom to another is required to effect the interchange of their charges. For suppose H, H, Cl, Cl (Fig. 4) represent respectively a hydrogen and a chlorine molecule, and suppose that the negative hydrogen atom is connected with the positive chlorine one by a conducting circuit. Then, if the negative charge of the hydrogen and the positive one of the chlorine were interchanged, the diminution in the potential energy due to the Volta effect would be $2(\sigma_{Cl}-\sigma_H)$, where σ_{Cl}, σ_H are the Volta coefficients of chlorine and hydrogen respectively, σ_H being negative. To set off against this diminution in the potential energy due to the Volta effect, we have the increase in the energy produced by tearing the $-$charge on the H atom from its proximity to the $+$charge, and forcing it close to the $-$charge on the Cl atom. The increase in potential energy due to this cause will be of the order $2(V_1+V_2)$, where V_1 and V_2 are the potential differences between the atoms in the hydrogen and chlorine molecules respectively. Thus the diminution in the potential energy when the charges are interchanged is

$$2(\sigma_{Cl}-\sigma_H)-2(V_1-V_2),$$

and the interchange will not go on unless this quantity is positive. Now the potential difference due to the contact of two substances is equal to the difference of their Volta coefficients, so that the σ's will not exceed a small number of volts. To estimate the V's is more difficult, but we may remark that when we produce a spark through a gas, in which case there is strong evidence that we split

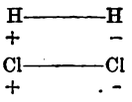

Fig. 4.

up some of the molecules into atoms, then, no matter how short the spark may be, or what may be the pressure of the gas, the potential difference between the electrodes must exceed a certain value, which is very large compared with the potential differences developed by the contact of heterogeneous substances, amounting in the case of hydrogen to between 190 and 200 volts. This minimum potential difference required to produce a spark is so constant under very varying physical conditions, such as pressure, spark length, and so on, as to suggest that it represents some property of the molecule; and I am inclined to think, and some experiments recently made at the Cavendish laboratory seem strongly to support the view, that the potential difference between the atoms in a molecule placed so as to be free from the action of other molecules is of the order of the minimum potential difference required to produce a spark. In the few cases where a direct estimate has been made of the work required to split up the molecule into atoms, such as that made by E. Wiedemann of the work required to decompose the hydrogen molecule, and that by Boltzmann for the iodine molecule, the potential difference indicated by these estimates far exceeds that produced by the contact of heterogeneous substances.

It would thus appear that in the case of gases where the molecules are free, the condition

$$2(\sigma_{Cl}-\sigma_H) > V_1+V_2$$

is not fulfilled; so that, on the electrical theory, chemical combination would not proceed. To produce chemical combination in such cases there must be some means of lowering the potential difference between the atoms in the molecules. Two methods by which this might take place at once suggest themselves. The first of these is that the combination, instead of taking place between a single pair of molecules, really takes place between aggregates of the molecules, physical aggregation preceding chemical combination.

Thus suppose that a number of molecules form themselves into a chain, such as that represented in Fig. 5; then, if we consider a $-$H atom and the adjacent $+$Cl one, we see that the disposition of the charges on the atoms of the other molecules in the chain will diminish the work required to separate the $-$ charge on the H atom from the $+$ charge on the neighbouring H atom, and also that required to separate the $+$ charge on the Cl atom from the $-$ charge on the atom with which it is paired. Thus, this disposition of molecules, by diminishing the electrostatic attractions, increases the chance for the $-$H and $+$Cl to interchange their charges in response to the "Volta effect": after this interchange has taken place the adjacent H and Cl atoms will have respectively $+$ and $-$ charges; *i.e.*, charges suitable for the formation of the HCl molecule; if such molecules form, the ring will be disposed as in

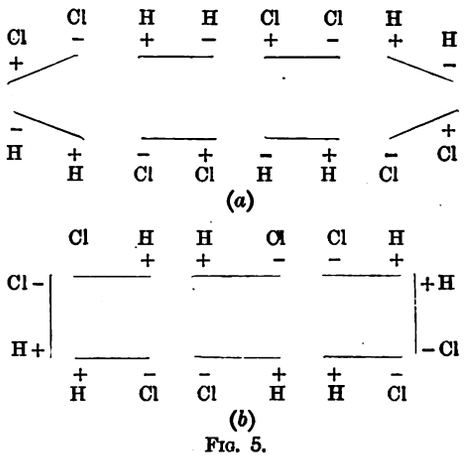

Fig. 5.

Fig. 5 (*b*). This disposition will not be stable, since the lines joining the negative to the positive atoms in the molecule do not all point in one way; the ring will consequently break up into separate HCl molecules.

(To be concluded).

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December 20, 1895.*

An Extensive Trolley Strike.—At the time of writing the street-car traffic in Philadelphia is almost entirely paralyzed through a strike of electric railway employés. The strike was caused by the refusal of the Union Traction Company, which has a practical monopoly of all street-car lines in the city, to accede to the demands of its employés, which are substantially as follows:—First, 10 consecutive hours shall constitute a day's work, for which $2 shall be paid; second, all work on snow ploughs or "trippers" shall be considered special work, for which extra compensation shall be allowed; third, the Company shall exercise every care for motormen, this referring to the "vestibule" compartment at ends of cars; fourth, no employé shall be discharged from the Company for his connection with labour organisations, and the large number recently discharged for such affiliation shall be reinstated. The strike was commenced on December 17th; during the first two days there was considerable violence, with the destruction of property amounting to about $10,000, for which the city will have to pay. A limited number of cars are now running under police protection. The prospects of the strikers gaining their ends are good, provided no more violence is used, principally through the sympathy of the public, which has an intense antipathy to the Union Traction Company on account of its recent policy of abolishing free transfers.

An Electrical Exhibition.—A Company has been organised to hold an electrical exhibition in New York City during the month of May, and is endeavouring to obtain the co-operation of the several national electrical professional organisations to the extent of holding their meetings in the same building in that month. The National Electric Light Association has met the wishes of the Company in this respect, and overtures are being made to the American Institute of Engineers. While the main purpose of the exhibition is purely commercial, it is intended to include a number of interesting features, such as working polyphase systems, spectacular effects, &c.

Cast Welded Rail Joints.—A contract has been given by the street railway companies of Boston and Providence for rejointing the rails of their lines by a new process. The process consists in casting a slug of iron around the joints, which

Digitized by Google

have been previously prepared by cleaning and the insertion of short wrought-iron plugs in the bolt holes of the rails made for the tie plates thus displaced. Expansion and contraction need not be allowed for, as experience has shown that the elasticity of the rails is sufficient for this purpose. and any poor joint is at once detected through being thereby drawn apart. This process is much cheaper than the electric welding one, and that it promises reliability is evident from the above large and conservative companies adopting it.

CORRESPONDENCE.

TELEGRAPHY IN LONDON: 1847-1896.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue I read with much interest the letter from my dear old friend Mr. J. W. Wilkins in connection with telegraphy in London in the early days.

I quite remember the fact of the Seymour-street office being the first public telegraph office in London, but he is in error in saying that that office was abandoned for that at Founders'-court, because the central telegraph office, as well as the general offices of the old Electric Company, were situated at 345, Strand (at which office I was in charge), in 1846.

Mr. Wilkins' letter is most interesting as a reminiscence of the remote past, and I wish he could be induced to give us more of his interesting reminiscences, as we have very little or no record existing of the early days of telegraphy, prior to the incorporation of the Electric Telegraph Company in March, 1846. He could, if he will, tell us a great deal, and I trust he will allow himself to be drawn out of his shell, and put on record facts which even I have a very hazy recollection of after a lapse of half a century.

I agree with you that the house in Seymour-street might be immortalised with a tablet recording the fact of its being the first public telegraph office not only in England, but in the world.—Yours, &c., W. T. ANSELL.

London, December 27, 1895.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir:—If I rightly understand the feeling of the large section of the Institution who, with its best interests at heart, are of opinion that the time has now arrived when some changes should be carried into effect, their desires may be comprised under two principal heads.

They are anxious, firstly, that the constitution and the manner of election of the Council should be so altered as to render the Council more truly representative of those who are actually doing the electrical work of the present day, more in touch with their requirements, more conscious of their desires and aspirations, more amenable to their wishes. Secondly, that the standard of qualification required for full membership of the Institution should be raised, so that such membership should be a real, and not as at present, a practically nominal distinction.

With a view to arriving at a satisfactory solution of these problems I beg to submit for consideration the following suggestions, which are, of course, only in outline, and are capable in some cases of considerable modification in detail.

1. Some curtailment of the growing preponderance of power at present vested in the permanent members of the Council as distinguished from the elective members.

2. An increase in the number of elective members of Council, so that all branches of the profession shall be more adequately represented.

3. A larger number of members of the Council to retire annually, so as to allow of the introduction of more fresh blood every year.

4. Greater facilities to be given for country members serving on the Council, it being understood that such country members of Council need not give such constant attendance at the Council meetings as is expected of members resident in London.

5. A much longer interval of time to elapse between the publication of the Council's nominations for new members of the Council and the date on which the ballot is held.

6. The list of nominations to be published at least one month before the issue of the ballot papers.

7. The ordinary members to be given an opportunity of adding names to the Council's nomination list, and names so added by ordinary members to be printed on the official ballot papers in such a manner as to be indistinguishable from those nominated by the Council.

8. The evening devoted to the annual general meeting to be reserved entirely for the necessary formal business and for discussion on any matters pertinent to the general affairs and welfare of the Institution.

9. Some alterations to be made in the constitution of the Institution, whereby for the future no one shall be qualified for election as a full member who is not actively engaged as a practicing electrical engineer or electrician, a new class being created, as in the case of the Institution of Civil Engineers, for those who desire to belong to the Institution, and whose association with the Institution may be of advantage to the latter, but who are not qualified for full membership.

None of the above suggestions can be said to be in any way revolutionary, one and all of them being taken from the regulations in force in other engineering societies older and more experienced than our own.

I believe that some changes in the direction indicated could not fail to be salutary, and would greatly increase the prestige, usefulness and harmony of the Institution as a whole.—Yours, &c., A. A. C. SWINTON.

December 31, 1895.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would not the following, which is a modification of Mr. Addenbrooke's proposal, put the matter in form?

Increase the number of members of the Council, say, to 24, and allot a certain number and one vice-president to each branch. Let each branch act as a committee, presided over by its vice-president, reporting to the whole Council for approval. This is practically the arrangement that rules in municipal councils, aldermen, or older members of the Council, acting as chairmen of committees. Each committee has its own work, and exercises certain powers within it own domain, reporting to the whole Council periodically. In the case of the Institution the arrangement should work even better than it does with municipalities. The presidential chair would be filled by a leading member from each branch in turn, so that there need be no room for jealousy between the different branches. As other departments of electrical industry are created, further batches of six, or whatever number may be arranged, could be added to the Council, just as additional members are added to a town council as its area and population expand.

May I suggest also that country members might receive more consideration than they now do? At present a country member obtains no advantage beyond a casual visitor. He pays his subscription for the benefit of his London *confrère*. I believe there is a very strong feeling among country members on this point, and that the formation of the Northern Society of Electrical Engineers is an expression of this fact.

With regard to the immediate cause of the present outbreak, I am strongly of opinion that the Council have done wrong in not recommending Sir David Salomons for the presidency, and that the members who have taken the action which has led to the recommendation of Dr. Hopkinson have also done wrong. The time for action, if any was necessary, was allowed to pass years since. Sir David is allowed to mount, step by step, till his foot is on the rung of the presidential chair, and is then thrust rudely back. He stands in the peculiar position, that while he has been judged worthy to fill the chair in the President's absence—perhaps a more difficult task than that involved in the presidential office itself—he is judged unworthy to preside in his own name. The members who have taken action this year could as easily have taken

Digitized by Google

action prior to one of the elections when Sir David qualified as Vice-president. Why did they not do so?

There is also another side to this question. Electricity is such a fascinating study that it has enlisted the services of a large army of wealthy amateurs, many of whom could hold their own with eminent practising electrical engineers. Should they not be represented? And should an eminent scientist be disqualified for a post of honour because the work is to him one of love and not of necessity?—Yours, &c.,

SYDNEY F. WALKER.

Cardiff Electrical Works, Severn-road, Cardiff.

THE PAST YEAR'S WORK.

MESSRS. JOHNSON AND PHILLIPS report that during the past year all the departments have been uniformly busy. The manufacture of alternators, dynamos, transformers and central station accessories has surpassed that of previous years. The firm have been very busy on several large contracts, which include transmission of power plants for South Africa, alternators for the St. Helens' Corporation, and the station plant for the Cape Town Electric Lighting Company. Orders for transformers continue to pour in, and the firm claim to have more transformers of their manufacture on circuit in this country than any other manufacturers. Several of 100 kilowatts are now being constructed and the sizes on order vary from this to half a kilowatt. The cable machinery department has been very busy on stranding, cable-making, and wire-covering machines both for this country and abroad, and have also had in hand the picking-up and paying-out machinery, accessories and stores forming the complete equipment for the Japanese Government's cable steamer. The arc lamp department has been kept exceptionally full of orders, especially during the latter part of the year, and nearly all the Corporation contracts of the year have been secured, including Portsmouth, Brighton, Taunton, South Shields and Edinburgh, also for the lighting of Johannesburg. The total orders are much in excess of the previous year. The new type of Brockie-Pell lamp introduced at the beginning of last year is rapidly gaining favour, the pattern being considered the best yet devised. The trade in carbons has also been exceptionally heavy. The cable department has been chiefly occupied during the year with the manufacture of vulcanised rubber cables for wiring purposes and underground use. High-tension concentric mains have been completed in connection with the lighting of London, Walsall and Malta, as well as a large quantity of single mains for various towns at home and abroad. The Brooks oil-insulated cables have been supplied for the wiring of the Glasgow Harbour Tunnels, the wires being insulated with oil right up to the incandescent lamp holder. The use of this system for this special class of work has been a great success. In the meter department every effort has been necessary to meet the steadily increasing demand, and standard designs for all sizes, from 5 to 1,000 amperes, have been prepared, in addition to those in use at the beginning of the year. From these designs instruments of all sizes have been stocked and sold. Very extensive additions to the instrument shops have been made for rapidly and accurately testing these instruments. The plant put down early in the year has been kept fully occupied and should the sales continue to increase at the same rate further additions will very shortly be needed. Messrs. Johnson and Phillips write in a very optimistic tone, and congratulate themselves on the work they have secured and executed during the year, regarding the outlook for 1896 as extremely hopeful.

Amongst the leading electrical firms who issue satisfactory reports for 1895 may be mentioned the ELECTRIC CONSTRUCTION COMPANY (LIMITED), who have had an unprecedented amount of work during the year and inquiries and orders for all classes of machinery. Generating plant of a special type has been manufactured and erected for the authorities of Wolverhampton, Stafford, Manchester, Halifax, St. Pancras (London), and for the electric supply companies of Liverpool, Birmingham, Chelsea, Oxford, Crystal Palace, Clerkenwell (London), &c., &c. In traction work the Company have successfully completed the contract for the Madras tramways. A large influx of orders for general electrical engineering work has necessitated the preparation of new catalogues, which have been issued during the year. Considerable progress has been made in the design and efficiency of the Company's dynamos, motors, continuous-current transformers, alternators and converters, arc lamps, switches and other apparatus. The number of employés has steadily increased, and important additions to the works premises and machinery are necessitated by the satisfactory increase of business. The work in hand includes a 500 H.P. dynamo for the War Office, a 300-kilowatt steam alternator for Halifax, motor equipment for the Liverpool Overhead Railway extension (some particulars of which were given in our issue for December 13th), and for the electrical equipment of the Hartlepool Tramways. These and other important orders in hand represent about six months' work.

Another branch of what may now fairly be termed the electrical industry which has shown considerable extension during the past year is that represented by Messrs. DOULTON AND CO.'s stoneware conduits. During 1895 this conduit has been used both for high and low-pressure electric supply schemes, amongst the districts supplied being Bedford, Portsmouth, Sunderland, Edinburgh, Chelmsford, Preston, Stafford, Oswestry, &c., and several of the London supply companies have adopted the conduit. Of course, several types of conduit and accessories have had to be devised to meet the varied requirements of electrical supply, and Messrs. Doulton have therefore wisely prepared a new catalogue for this branch of their business. Bare copper mains are not everywhere regarded with favour, but Messrs. Doulton inform us that there has been scarcely any diminution in the demand for the insulators which they have supplied for some years past for these mains. Both the London and Staffordshire works of the firm have been busy during the year with large orders for insulators for telegraph, telephone and electric traction purposes, as well as for battery jars, porous cells, plumbago crucibles and the many other Doulton manufactures used in various branches of the electrical industries. A distinct branch of Messrs. Doulton and Co.'s business is the manufacture of plant for the softening and purification of water for boilers and manufacturing purposes, amongst the contracts executed during the year being one for a complete water-softening plant for the new St. Pancras electric supply station at King's-road.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is in active preparation, and will be ready at the end of January. Orders for Advertisements and Subscriptions (6s. 9d. post free, abroad 6s. 6d.) should now be sent in. Full particulars post free on application.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

TENDERS INVITED.—The St. Pancras Vestry invite tenders for wiring and other work in connection with the electric lighting of the Vestry Hall and Offices in Pancras-road. Specification, &c., can be obtained at the Electricity Department Offices, 57, Pratt-street, N.W., and tenders must be sent in to Mr. A. E. Pycraft, at the Pratt-street Offices, by 12 noon of the 16th inst. Some further particulars are given in our advertisement columns.

Digitized by Google

TENDERS INVITED.—The Posen Direction of the Prussian State Railways require tenders for the supply of 90,000 arc-lamp carbons. Tenders to the Königliche Eisenbahn Direction, 40, St. Martin Strasse, Posen, by the 10th instant.

——— The Hanover Direction of the Prussian State Railways invite tenders for the supply of 1,100 telegraph poles. Tenders to the Königliche Eisenbahn Direction, Hanover, by the 16th inst.

——— The Municipal Authorities of Brünn (Austria) invite tenders for the establishment of an electricity generating station in the town for supplying electrical energy for lighting and power purposes, including the supply of current for an electric tramway. Tenders to the Burgmeisteramt Brünn, by March 1st.

TENDERS ACCEPTED.—The Gas and Electric Lighting Committee of the Aberdeen Town Council have accepted the following tenders for stores for the ensuing year :—

J. Abernethy and Co., for ironwork	£374	14	0
Glegg and Thomson, for malleable iron and steel	149	6	8
J. Blaikie and Sons, for brasswork and lead and tin work	264	13	8
Stewart and Co., for tubing	417	13	4
G. Walker, for engine and exhauster	584	0	0
J. Wallace, for iron girders	388	17	0

BUSINESS FOR DISPOSAL.—Our advertisement columns contain brief particulars of a well-established electrical manufacturing and contracting business for disposal in London, with a present turnover of about £11,000 per annum.

NEW WORKS.—The site for the new works of the Castner-Kellner Chemical Company has been fixed at Western Point, Runcorn, where it is anticipated the new factory will provide employment for many hands. It is proposed to erect an electrical plant, equal when finished to 4,000 H.P., at an estimated outlay of £130,000.

ADDITIONAL PLANT.—The Newcastle-upon-Tyne Electric Lighting Company have ordered from the Brush Company a 300-kilowatt Mordey alternator, this making the sixth machine of this type in the station, and brings the total capacity of the station up to 900 kilowatts.

CHANGE OF ADDRESS.—Messrs. F. Wiggins and Sons, mica merchants, owing to increase of business necessitating additional warehouse room, have purchased 103, Minories, and during the demolition and rebuilding of this and their old premises adjoining, have taken temporary premises at 62 and 63, Minories, where (or to their other establishment, 10, Tower-hill, London) for the next twelve months all communications should be addressed.

——— Messrs. W. F. Dennis & Co. have now taken possession of their larger premises at 23, Billiter-street, London, E.C., *vice* No. 11, in the same street.

APPOINTMENT.—Mr. Thomas Bell has been appointed representative by Messrs. Heaton and Co., electrical engineers.

DISSOLUTIONS OF PARTNERSHIP. — The partnership firm of McKinley, King Smith and Co., iron merchants and electrical engineers, of Upper Thames-street, E.C., has been dissolved; as has also the firm of Baker, Hill and Co., electrical engineers, decorators, &c., of Oxford.

LIQUIDATIONS.—A meeting will be held on the 25th instant, at 12 o'clock, at 401 and 402, Mansion House-chambers, Queen Victoria-street, E.C., to receive an account of the winding-up of the Electric Lighting and General Development Syndicate (Limited).

——— In the Chancery Division of the High Court of Justice, Mr. Justice Vaughan Williams on December 4th made an order that the voluntary winding-up of the Herculite and Electrical Manufacturing Company (Limited) be continued, but subject to the supervision of the Court.

——— Mr. W. Izard, 52, Gracechurch-street, E.C., has been appointed trustee in the bankruptcy of Smeaton and Page, electrical and general engineers, 135, Minories, London, E.

——— Notice is given of the release of the trustee (Mr. J. Bowling) in the bankruptcy of Harry Austin and James Myers, lately trading as electrical engineers under the style of Austin and Myers, at Armley, near Leeds.

DISCHARGE.—An application is to be made at the Bankruptcy Court on the 16th inst., at 11:30 a.m., for the discharge of Walter Andreae, lately trading as an electrical engineer at 132, Hurlingham-road, Fulham, and 62, Vauxhall Bridge-road, S.W.

WIRE CONTRACT.—The contract for gutta-percha wire for use by the National Telephone Company for the year 1896 has, we understand, been secured by the United Gutta Percha and Rubber Company (Limited), of Craig Park Works, Townmill-road, Glasgow.

BELTING TABLE.—A useful, and, as far as we have tested it, reliable belting table is issued by Messrs. J. W. Cable and Co., of Clerkenwell-road, E.C. Measurements of belting required to transmit any given horse-power from pulleys of 8in. to 60in. diameter and 90 to 200 revolutions are given, with examples for the use of the table, which are simple.

DIARIES.—Not the least useful annual publication which reaches us is Messrs McCorquodale and Co's "Railway Diary and Official Directory" for 1896, which, besides being a useful size, gives a large quantity of valuable information to those having dealings with the railway companies and their officials in this country. The information is given in a compact form, and there must be many electrical firms to whom it would be useful. The published price is 1s.

CALENDARS, &C.—We have received from the Eastern Telegraph Company copies of their Paper Knife and Calendar for 1896. On the paper knife, as usual, is legibly printed in colours a map showing the routes of the submarine cables of the world.

——— Messrs. Street & Co., the well-known advertising contractors, of Cornhill, E.C., and Serle-street, W.C., send a handsome framed Calendar worked in colours.

——— From the Commercial Cable Company a neatly-printed hanging Calendar is to hand, which, in addition to serving the useful purpose of a day-to-day indicator, contains a quantity of information concerning the Company's offices, &c.

——— From the Direct Spanish Telegraph Company we have received a highly-coloured calendar, of Spanish origin, with a date calendar of the bold and fearless type. Those of our readers interested in flag lore or in heraldry will be especially interested in this calendar.

THE "ENGINEERING MAGAZINE."—The January number of this magazine is now ready, and fully maintains its high standard of excellence, both in the variety of the subjects dealt with and the excellence of its illustrations. The articles in the current issue include :—"Representative Money and Gold Exportations," by Horace White ; "Cripple Creek Gold Mines and the Stock Boom," by T. A. Rickard ; "Future of the American Iron Trade," by J. M. Swank ; "Are American Railway Rates too High?" by H. T. Newcomb ; "An Engineer's Life in the Tropics," by C. P. Yeatman ; "Are we Educating too many Electricians," by H. Floy ; "The Location and Construction of Dams," by J. B. Johnson ; "The Value of Good Architecture in Cities," by Barr Ferree ; "A Piece-Rate System and Shop Management," by F. W. Taylor; and "The Law of Water and Irrigation," by R. J. Hinton. The usual exhaustive review of the World's Press is also given. This number, as well as all the back numbers, may be obtained at the offices of the European edition, 1, 2, and 3, Salisbury-court, Fleet-street, London, E.C. A complete index to the main articles in the magazine from the commencement in April, 1891, is now ready, and will be forwarded post free on request.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—It is important that all entries for the 1896 edition of the well-known Blue Book should be sent in at once to the publisher, 1, 2 and 3, Salisbury-court, London. The book will be published about January 31st, and will contain many new features of interest to the electrical and allied trades, as well as the old features brought up to date. The business changes in January, which will apparently be exceptionally heavy this year, will be fully recorded. This is an important matter, and makes the book of special value. Orders for subscriptions and advertisements should be sent in at once.

ABERDEEN.—The sub-committee recently appointed to consider the question of electric motors have presented their report, and it has been decided to invite some of the principal makers to forward motors of various designs for exhibition in the Corporation's shop in Union-street.

BILSTON.—The new public baths and waterworks are lighted electrically. The installation has been carried out by the Universal Electric Light and Power Company. The electroliers are of a special design, and were manufactured by the Edison-Swan Company.

BRADFORD.—In view of the extension of the Corporation electricity works, the members of the Electricity Sub-Committee are visiting some of the neighbouring electricity supply stations before making any definite recommendation as to the nature and scope of the extensions.

BRADWELL (YORKS.).—Mr. John Hall, a machine smith, has recently installed the electric light in his business premises at Bradwell. He rents from the District Council an overflow from the waterworks reservoir, which gives him sufficient power to work a dynamo of his own construction, from which he derives current for lighting his two shops in Bridge-street.

CANADIAN IMPORT DUTIES ON ELECTRIC BELLS.—The Canadian Comptroller of Customs recently decided that the duty on electric bells imported into the country should be 25 per cent. *ad valorem*.

CANADIAN MICA TRADE.—At a recent meeting of the representatives of the mica-producing firms in the province of Quebec, it was decided to form an association for the purpose of regulating prices. The association purpose also that the selling price of all mica exported be based on the value of mica in Canada governed by grades.

CHURCH LIGHTING.—The Catholic church of St. Joseph's, Banbridge, Ireland, is now lighted electrically, the work having been

Digitized by Google

carried out gratuitously by Mr. E. Geoghegan, proprietor and manager of the Banbridge Foundry Company.

COLCHESTER.—At the meeting of the Town Council on Wednesday the special report by the Lighting Committee on the electric lighting question was discussed. The report stated that an important communication had been received from the officer commanding the Royal Engineers in the Eastern District in reference to the lighting of certain military premises. In view of the contents of this letter, the Lighting Committee recommended that steps be taken to put the Colchester Provisional Electric Lighting Order in operation, that they be empowered to instruct their consulting electrical engineer (Mr. W. H. Massey) to prepare plans and specifications for the establishment of electricity works in the town, to make application to the Local Government Board for sanction to borrow the necessary money for the carrying out of the scheme, and also to make provisional arrangements with the War Department for the supply of electric current. A long discussion took place, and the further consideration of the matter was deferred till the 16th instant.

CORK.—It having been stated that a recent fire at the Munster Arcade, Cork, had been caused by the fusing of electric light wires, Messrs. Handley and Shanks, in a letter to the *Cork Constitution*, go into particulars on the subject. The writers point out that owing to the fire inquiries have been made as to the liability to similar outbreak through electric lighting installations, and after pointing out that representatives of fire insurance companies have rules to guide them, which insure almost complete immunity from risk, Messrs. Handley and Shanks give an extract from the table issued officially by the Metropolitan Fire Brigade of the number of fires within the metropolitan area and the causes thereof for the three years 1892-1894, as follows:—Candles 567, gas 833, oil lamps 1,305, electric 9.——The Cork Chamber of Commerce and Shipping have approached the postal authorities with a view to their erecting a trunk line between Cork and Dublin, thus putting the former city in telephonic communication with London. No definite reply to the request has as yet been given, but the Postmaster-General has caused inquiries to be made as to the probable revenue from the suggested line.

COVENTRY.—A circular issued by Mr. G. S. Ram, of the Coventry Municipal Electricity Works, calls special attention to the opportunity which the introduction of the electric light into Coventry offers the owners of factories and workshops to overcome the penalty clauses of the Factory Act so far as they refer to the provision of extra air space during overtime hours. The circular is as follows:—

"The Factory Act, which comes into operation January 1, 1896, prescribes the minimum air space to be allotted to each person employed in a factory or workshop. The Home Secretary may raise this minimum for any period during which artificial light other than electric light is employed for illuminating purposes. The use of the electric light in a factory or workshop thus excludes the operation of any order made by the Home Secretary under the above provision, and enables the same number of persons to be employed during the period of artificial illumination as by daylight."

This is a most important matter for owners who have only limited workshop space, and should lead to many orders for wiring for the electric light where current is readily obtainable. In certain industries (such as the printing trade), in which much overtime is worked at certain seasons, this point will be fully appreciated.

EALING.—The Electric Lighting Committee have just presented a very favourable report on the progress of their electric light undertaking. Applications for 6,436 8 c.p. lamps have been received, and 5,353 have already been connected. Additional machinery, capable of supplying current to 3,000 lamps, is being put down, and the popularity of the installation had been so great that it is difficult to keep pace with the demand.

EDINBURGH.—The Electric Lighting Committee have decided to recommend that the following streets be lighted electrically:—South Clerk-street (at Literary Institute) to Salisbury-place, Waterloo-place to Abbeyhill, Lauriston to Tollcross, Dalry-road from Haymarket to Ardmillan-terrace, Fountainbridge from Freer-street to Viewforth, Greenside to Pilrig, Frederick-street to Comely Bank, Hanover-street to Cannonmills, and Cowgate (from Grassmarket) to St. Mary-street, at a cost of about £2,630.——The National Telephone Company recently suggested that the Corporation should lay underground tubes for telephonic purposes at the Company's expense; but the Sub-Committee to whom the matter was referred recommend that the proposal be not entertained.

ELECTRICITY IN MINING.—An electric lighting installation has recently been carried out in the Brilliant Gold Mine, Queensland, by the Australian branch of the Brush Company.

FACTORY LIGHTING.—Recent contracts carried out by the Banbridge (co. Down) Foundry Company include the premises of the Damolly Linen Weaving Company, the Boyne Weaving Company (Drogheda) and the Hazelbank Weaving Factory (Lawrence Town). For the former installation water power is utilised, and at the Boyne Factory the installation consists of over 1,000 lamps, being one of the largest in Ireland. The Foundry Company are described as manufacturers of their own electrical apparatus.

GLASGOW.—The Glasgow Corporation gas and electric lighting treasurer (Mr. James Fleming) reported to the Sub-Committee on finance on December 26th that the electric lighting rents collected for the year commencing on June 1st, 1895, amounted to £5,389. 8s. 5d., compared with £5,221. 18s. 5d. for the corresponding portion of the financial year 1894-95, an increase of £167. 10s. An interesting series of articles on Glasgow and its tramway system is appearing in the *Glasgow Herald*.

HANLEY.—The parish church at Shelton is being fitted throughout with an installation of incandescent lighting by Mr. Wm. Hodgkinson, of Hanley. The installation will also comprise an electric motor for blowing the organ.——The extensions at the Corporation electricity works are being pushed forward with the utmost rapidity, the engineers hoping to be able to supply double the number of lamps at the end of the present month.

HIGH WYCOMBE.—Some time back the Electric Lighting Committee received certain proposals from Messrs. Pritchetts and Gold for the transfer to them (or to a company to be formed by them) of the High Wycombe Provisional Electric Lighting Order. The suggested terms of transfer were as follows: (*a*) A contract for ten years to be entered into for the lighting of all the present street additional lamps that may be required at the price of £3 per annum per 16 c.p. lamp. Hours of lighting and other conditions to be similar to those in the present contract with the gas company. (*b*) Electric current to be supplied to private customers at the rate of 8d. per unit. The Corporation to undertake to take current at this rate for all municipal buildings and offices. (*c*) The Corporation to have the option of purchasing the undertaking at the expiry of seven years from the date of commencing public lighting on paying a sum equal to the amount expended plus a profit of 15 per cent. If the Council failed to exercise their right of purchase at the end of seven years they would have the further option of purchasing at the expiry of 14 years on similar terms, but with the addition of 10 per cent. profit, and in this case one year's notice of intention to purchase to be given by the Corporation. (*d*) The Council to give an engagement that the machinery and undertaking should be exempt from rating. (*e*) Finally, the Council would have to stipulate that no other company or firm should supply electric current during the continuance of the Provisional Order. The Committee were willing to accept these terms, subject to an approved agreement being entered into and to the following modifications:—(1) The licence to exercise the powers under the Order to be for a term not exceeding 21 years; (2) the stipulation as to rating of machinery to be withdrawn; (3) the contract for public lighting to be for seven instead of ten years, and the price per lamp to include repairs; (4) the firm to defray the cost (£246) of obtaining the Order; and (5) any election to purchase the works by the Corporation to be by six months' notice at any time upon the terms mentioned in the tender. Messrs. Pritchetts and Gold, however, declined to accept these stipulations, but were willing that the Council should have purchasing powers at any time after 14 years on six months' notice, and to accept other modifications by which the contract for public lighting is to be for 14 years, and the cost of obtaining the Order to be refunded by the Corporation in the event of their exercising their purchasing rights. The entire question was discussed at considerable length at the last meeting of the Council, and it was finally decided to refer the further consideration of the matter back to the Committee, with power to arrange the details of the contract.

ISLINGTON.—The Lord Mayor of London will perform the opening ceremony at the electric lighting station in Eden-grove.

LECTURES.—Before what is described as "a fairly good attendance" at the Royal Institution, Hull, on Tuesday, Prof. V. B. Lewis, Professor of Chemistry at the Royal Naval College, lectured on "Flame." The British Gas Light Company had very kindly fitted up the lecture hall with incandescent burners "with all the latest improvements," and Prof. Lewes was good enough to describe "the bright incandescent gas light" as the light of the immediate future. Many of the lecturer's remarks were of a similar harmless and instructive character. A local journal, in its account of the lecture, states that the incandescent gas light is "pronounced by oculists as the best light for the eye, being the nearest approach to daylight." This will probably surprise the Hull folks, who have had some years' experience of the electric light.

NEWCASTLE.—The British Thomson-Houston, Limited, have laid before the City Council an offer to equip and work the Newcastle Tramways electrically, for a sum not exceeding £86,000, or about two-thirds of the estimated cost of the cable system. The scheme will be discussed by the Council at its next meeting. The Company ask the Council to seriously consider the subject before embarking upon a large outlay for cable traction in view of the fact that cable lines in the United States are being in a number of cases replaced by electric systems.——Discussing the rival systems of haulage, Mr. Phillips Dawson delivered a lecture before the Tyneside Geographical Society on Monday, at which Captain

Digitized by Google

Noble presided, and a large audience assembled, including many of the town councillors and leading merchants of the town. After an interesting discourse, in which Mr. Dawson pointed out the advantages of electric traction, the lecturer answered a number of questions to the general satisfaction of those present. Figures showing the great advances made by electric over other systems of haulage were also given. A cordial vote of thanks to the lecturer was unanimously agreed to.——In their estimates for 1895-6 the City Lighting Committee have made provision for 24 additional arc lamps for lighting some of the new streets in the Byker and Heaton districts.

NEWMARKET.—The District Council have decided to oppose the application of the Newmarket Electric Light Company's for a Provisional Order.

NEW YEAR'S HONOURS.—Amongst the list of New Year's honours appears the name of Major J. S. Goldie Taubman, Speaker of the House of Keys and Chairman of the Douglas Southern Electric Tramways (Limited), who has been created a knight.

OGWEN (NORTH WALES).—At the last meeting of the District Council it was decided to authorise the Bangor Town Council to include the district in any application they might make to the Board of Trade for a Provisional Electric Lighting Order.

OLDHAM.—In accordance with Prof. Kennedy's recommendations, the Electric Light Committee of the Town Council have instructed their electrical engineer to prepare plans and particulars of extensions to the plant at their electricity station.

PRETORIA (SOUTH AFRICA).—A Reuter's telegram of the 28th ult. states that the Boer Government contract for the establishment of electric lighting in the town which is just issued forbids the use of English-made plant, and provides that only that made on the Continent shall be adopted. In reference to this matter the following letter appeared in the *Standard* of Wednesday over the signature of "One Who Knows":—

"Appearing as it does at the present juncture the statement that the Government of Pretoria has interdicted the use of English plant in its electric lighting might be interpreted as an unfriendly act to England, but in reality it is not so. The electric lighting of Pretoria, under Government management, has been in full operation for more than two years; but the original plant, which was sent from England, proved to be of very inferior quality, and is already worn out. It is natural, therefore, that the Government of Pretoria should get their new plant from some other country."

This statement received prompt denial from the English firm who constructed and erected the plant, who replied as under:—

"The statements are not only incorrect, but very misleading. The plant is in perfect repair and eminently satisfactory, the engineer in charge of the lighting station having recently stated to one of our engineers, who has lately returned from South Africa, that no plant could run more satisfactorily than that under his charge. As regards the underground cables, which have caused some trouble, no blame can be attached to the makers, the only mistake being that a class of cable was chosen unsuited to the peculiar nature of the soil. We do not, therefore, see how the performance of the present plant, which has been running nearly four years, can be said to have given rise to the decision referred to. We do not suggest that any unfriendly act is meant by interdicting English plant, but only suppose that, as in other cases, influence has been brought to bear by some Continental firm in favour of their own plant to the exclusion of others."

It is somewhat surprising that a leading English paper should allow a direct charge of this kind to appear over a *nom de plume*. To be effective such charges should be made with the full measure of responsibility attaching to them.

REDUCTION IN TELEGRAPH RATES.—The Commercial Cable Company announce that, as from the 1st instant, the rates to the following places will be reduced to 1s. 3d. per word:—Burlington, Clinton, Cedar Rapids, Davenport, Dubuque, Fort-Madison, Keokuk, and Muscatine (State of Iowa), Hastings, Redwing, Stillwater, and Wabash (State of Minnesota), Hannibal and Louisiana (State of Missouri).

REDUCTION IN TELEPHONE TRUNK LINE RATES.—The Treasury have sanctioned a reduction in the scale of charges for trunk telephone communication. The new scale, which comes into operation on January 1st, is as under: For 25 miles, 3d.; for 50 miles, 6d.; for 75 miles, 9d.; for 100 miles, 1s. For every additional 40 miles or fraction thereof, 6d.

ROCHDALE.—The Library Committee have decided to recommend the Town Council to light the Free Library by electricity, and to apply to the Local Government Board for sanction to borrow £500 to defray the cost of the installation.

ROTHERHAM.—At the last meeting of the Electric Light and Tramways Committee it was decided to recommend the Town Council to oppose the application of the Sheffield District and Rotherham Tramways Company's Bill for the construction of electric tramways in the district.

SOUTH AFRICA.—An application was recently made to the Town Council of Kingwilliamstown for a ten years' concession to light the town by electricity. The concession was not granted.

SOUTH STAFFORDSHIRE TRAMWAYS.—A further extension, until March 25th next, has been granted by the Board of Trade to the South Staffordshire Tramways Company for working the steam sections of their tramway system. The extension was opposed by the local authorities through whose districts the trams run, and the matter aroused a considerable amount of local interest.

STAPLETON (BRISTOL).—At the meeting of the District Council on Wednesday last it was decided to oppose the application of the Great Western Electric Light and Power Company for a Provisional Order for the district. At the same meeting a letter was read from Mr. D. Travers Burgess, on behalf of the Bristol Electric Lighting Committee, stating that, as the Corporation were proprietors of electricity works within the district, his committee had requested him to inquire whether the Council intended to oppose the application of the Great Western Company, and, if so, as to the nature of such objection. It was decided to reply that the matter was under consideration.

SWANSEA.—The Town Council again discussed the proposed electric lighting, dust destructor and tramway schemes on Monday last. The meeting was called for the purpose of formally empowering the Council to proceed with its Bill in the next session of Parliament. At the commencement of the proceedings a deputation waited upon the Council to urge the postponement of the schemes for at least twelve months. Mr. R. Martin (Chairman of the Tramways Committee) then moved that the Council be empowered to proceed with the Bill, and said that under the scheme the Corporation would in 24 years' time become possessed of its tramways without paying a penny for them. He referred to the Bristol Tramway Company, whose receipts had in short a time increased from £200 to £800 or £1,000 a week as a result of the introduction of electric traction. The tram lines of the town were at present in a sad state, but under the proposed arrangement they would be renewed, and the Company enabled to work them at a profit. By getting the Company as customers for their "day load" they would be enabled to sell electric current for lighting purposes at 3d., and even at this figure the Corporation would still make a profit. Even assuming that they could not obtain sufficient power from refuse destruction, and that they had to burn coal in order to obtain the necessary power, the total cost (including sinking fund) would be only £5,879 a year. 275,000 units at 3d. per unit would amount to £7,503. 16s. 8d., leaving a profit of £1,695 per annum, while with a production of 1,533,000 units per annum they could sell electrical energy profitably at 1d. per unit. Mr. Martin dealt very fully with the arguments in favour of the scheme, and gave it as his opinion that the street lighting would be effected free of cost to the ratepayers and surplus power could be disposed of at 3d. per unit. They had not finally made up their minds as to the dust-destructor scheme. It was absolutely necessary that a new method of disposing of the town refuse should be adopted. This scheme was the best means of destroying the refuse, and whatever power could be obtained from it should be applied to the relief of the rates. The motion was carried by 30 votes to 7.

TELEGRAPHIC COMMUNICATION WITH BUENOS AYRES.—We have received the following communication:—

"Our attention has been called to a pamphlet lately circulated amongst merchants, purporting to give, from certain examples, selected from 26 days out of a whole year, a statement of the average time of transit of cable messages exchanged between London and the city of Buenos Ayres. The time is stated to be—

By the direct route, *via* Lisbon, Madeira and Brazil (about 7,280 miles) ... ... 108 minutes.
By the Galveston route, *via* United States, Mexico, Central America, Peru, Chili and Argentina (about 11,960 miles) ... ... 80 minutes.

The undersigned have had the whole of the messages for all the dates in 1895 given by the pamphlet carefully examined, and find that the average time occupied by the messages sent over the Lisbon-Madeira route was 75min. only, and not 108min., as incorrectly stated by the pamphlet. One statement being found so exceedingly inaccurate, you can form your own opinion as to what reliance can be placed upon the other, which is put forward for purposes that are manifest.

"For the Western and Brazilian Telegraph Company (Limited),
"R. M. CUNNINGHAM, Secretary.

"For the Brazilian Submarine Telegraph Company (Limited),
"RICHARD COLLETT, Secretary."

THEATRE LIGHTING.—The New Grand Opera House, Belfast, is lighted throughout electrically.

THEFT—A driller named Morrison was charged at Bradford with stealing tools, the property of Messrs. Roslin and Matthews. He had been in the prosecutor's employ, but was discharged. Remanded.

TORQUAY.—A meeting of the Electric Lighting Committee was held on Tuesday last for the purpose of selecting a site for an electricity generating station. Several sites were proposed, but the Committee adjourned without coming to a decision. When a site has been selected, the consulting engineer (Mr. W. H. Trentham) is to submit an amended report and estimate of the cost of the Council's suggested electric lighting scheme.

TUNBRIDGE WELLS.—At the last meeting of the Town Council, Councillor Strange, in discussing the Lighting Committee's report, complained of the neglect to light the side streets at night. The electrical engineer (Mr. H. L. P. Boot) explained that the new machinery would soon be ready to meet extensions and the promise

Digitized by Google

of a contiuuous supply of current. Sir David Salomons said they must do everything possible to meet local convenience and retain the confidence of the public in the success and advantages of the electric light, and the Committee undertook to remedy defects in the lighting of the side streets as far as possible.

WALSALL.—The local papers express their satisfaction at the success of the electric lighting installation in the town. Full advantage was taken of the Electric Lighting Committee's permission for those connected to use the current one week free of charge, but this generosity will probably prove remunerative in the long run.

WARMLEY.—The District Council have decided to oppose the application of the Great Western Electric Light and Power Company for a Provisional Order for the district.

WHITECHAPEL (LONDON).—The Board of Works recently had a proposal from the Commissioners of Sewers for the erection of four arc lamps on the east side of Middlesex-street (which is within the Whitechapel district), and for supplying current to the same upon condition that the Board pay the cost thereof. The Committee to which this matter was referred recommended that the proposal be not accepted, and this recommendation was agreed to at the last meeting of the Board.

WIDDRINGTON.—The Widdrington Mechanics' Institute is now lighted electrically. Eight 95 c.p. lamps are employed for illuminating the billiard room.

WIMBLEDON.—At the last meeting of the District Council a letter was read from the Local Government Board with reference to the Council's recent application to borrow £32,000 for electric lighting purposes. The letter stated that, in view of the early expiration of the electric lighting licence of 1889, the Board would not sanction the loan for any period longer than the unexpired term of the licence. If, however, the Council were anxious to carry out the scheme by means of borrowed money, the matter would have to stand over until the Council could show that they had obtained new powers. The Chairman and Clerk were appointed to wait upon the Secretary of the Board in reference to the matter.

ANNUAL DINNER.—The employés of Mr. R. W. Paul, of Hatton Garden, E.C., were entertained at the Holborn Restaurant on New Year's Eve, the occasion being the first annual dinner.

NEW COMPANIES, STATUTORY RETURNS, &c.

KAMM'S ZEROGRAPH SYNDICATE (LIMITED).—This Company was registered on December 27th, with a capital of £12,000, in £10 shares, to enter into an agreement with Leo Kamm, inventor and electrician, of Hornsey-rise, London, N., to acquire or take licences for the user of any patents, rights, or privileges for the use, sale or manufacture of any telegraphic apparatus, or any instrument or appliance for the transmission of messages; to carry on any business connected with telegraphy or type writing, and to establish and carry out any system of telegraphy. The first subscribers, with one share each, are: Leo Kamm, inventor and electrician; H. F. Hoveler, S. Reuschel, F.W. von Limburg, C. Hess, H. Hempel, and J. W. T. Cutlan. The first Directors are Leo Kamm and S. Reuschel.

LIGHTNING EXPRESS RAILWAY SYNDICATE (LIMITED).—This Company was registered on December 23rd, with a capital of £100,000, divided into 25,000 £10 per cent. Preference and 75,000 Ordinary shares of £1, to acquire the inventions of Fritz B. Behr, civil engineer, in connection with lightning express or high-speed railways, and in connection with improvements in carriages and electric locomotives for such railways, and the sole and exclusive licence to use the inventions belonging to the Lartigue Railway Construction Company (Limited), for the purpose of building, equipping and working lightning expresses or high-speed railways, and to carry on the business of constructors of railways and tramways of all kinds, and particularly of those with a single rail, on the Lartigue system of construction; railway, mechanical and electrical engineers, and the business of a telegraph, telephone and electric light company in all its branches. The first subscribers are: Leonard Clow, stockbroker; Cecil G. Lindo, solicitor; Lieut.-Col. Sydney F. Foster; Benjamin G. Lake, solicitor; Fritz B. Behr, civil engineer; Arthur J. Sanderson, financier; and Norman S. Russell, civil engineer.

MADEIRA ELECTRIC LIGHTING COMPANY (LIMITED).—This Company was registered on December 23rd with a capital of £20,000, in £1 shares, to carry into effect an agreement between Harris Ullathorne and Arnold Hartley, electrical engineers, of Bradford, and the Company, for the acquisition by the Company of a concession granting the right to supply electric light to the City of Funchal, Madeira, with electricity for lighting, power and other purposes, and to carry on the business of electricians, engineers and contractors, suppliers of electricity, and manufacturers of and dealers in electrical plant, apparatus and materials.

OTIS STEEL COMPANY (LIMITED).—This Company was registered on December 20th with a capital of £450,000, divided into 33,000 Preference shares of £10 each, and 30,000 Ordinary shares of £4 each, to carry into effect an agreement with the Otis Steel Company (Limited), and Alexander Young, its liquidator, to acquire the shares, stock, debentures, debenture stock and other securities of the Otis Steel Company, of Cleveland, Ohio, U.S.A., or any other American company, and to carry on the business of metal manufacturers, workers, founders, forgers and refiners, smelters, &c. The first Directors are: Jeremiah Head, civil engineer, Josiah T. Smith, and J. E. Touch, consulting engineer.

ROAD MOTOR ASSOCIATION (LIMITED).—A Company was registered on December 20th, with a capital of £15,000, in £1 shares, to, amongst other things, carry on business as electricians, mechanical engineers, wire drawers, tube makers, metallurgists, &c.

RAILWAY AUTOMATIC ELECTRIC LIGHT SYNDICATE (LIMITED).—The annual return to October 3rd has only just been filed. The capital is £25,000, in 400 Ordinary and 600 Preference shares of £25 each; 396 of the former and 586 of the latter have been taken up, 200 Ordinary have been issued as fully paid, and the full amount has been called on the remainder.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 30½d. per oz. (Jan. 2nd). Consols (2¾ per cent.) 106¼–106⅜ for money, 105⅞–106⅛ for account; 2½ per cent. 102¾–103¼ (Jan. 2nd). Stock Exchange Settling Days: Consols, Jan. 3rd; Stocks and Shares Continuation Day, Jan. 14th; Ticket Day, Jan. 15th; Pay Day, Jan. 16th.

SIR W. G. ARMSTRONG, MITCHELL AND CO. (LIMITED).—At a special meeting of the shareholders of this Company, on Tuesday last, it was unanimously decided to adopt the reconstruction scheme referred to in our last issue, and at the same time to increase the ordinary capital of the Company to £3,000,000. A statutory meeting for the confirmation of this decision will be held on the 15th instant.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended December 29th were £890, against £858 in the corresponding week of 1894, an increase of £32. The total receipts for the half-year amounted to £23,443, against £23,305 for the corresponding period of 1894, an increase of £138.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The warrants for the interest due on this Company's £300,000 5 per cent Debenture stock have been posted.

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED).—The annual meeting of this Company took place at Leeds on Tuesday last, Mr. J. J. Atkinson presiding. The Chairman explained an arrangement whereby the Company would be enabled to start the new year unencumbered by any old losses. He said the Company's sales had steadily improved since the beginning of the past year, when the sales of copper sheets were only a few tons monthly. Further progress was only stopped by lack of capital; but he stated that in a short time a scheme would be submitted for greatly increasing the Company's resources to meet the demand for high-class and higher-priced articles. It has been decided to issue £7,000 worth of Six per Cent. Debentures, and more than half have been already applied for.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 29th inst. amounted to £941. The amount for the corresponding week last year was £837; increase, £104.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have received telegraphic advice stating that the necessary authorisation for the purchase of the Company's line has been continued by the Brazilian Chamber of Deputies and the Senate, and is again included in the Budget for the coming year. This Company's traffic receipts for the week ended December 27th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,329.

WESTERN UNION TELEGRAPH COMPANY.—This Company have issued their report for the quarter ended December 31, 1895:—The following statement, dated December 11th, exhibits the condition of the Company at the close of the quarter ended September 30, 1895:—

Surplus July 1st, as per last quarterly report.....		$7,447,476 35
Net revenues, quarter ended June 30, 1895.....		1,842,648 96
		$9,290,125 31
From which deducting for—		
Dividend of 1¼ per cent. paid October 15	$1,191,945 00	
Interest on bonded debt	223,557 32	
Sinking funds	20,000 00	
	$1,435,502 32	
Left a surplus October 1st, ...		$7,854,622 99
The net revenues of the quarter ended December 31st, based upon nearly completed returns for October, partial returns for November, and estimating the business for September, would be about.....		1,700,000 00
		$9,554,622 99
From which appropriating for—		
Interest on bonds	$223,550 00	
Sinking funds	20,000 00	
		243,500 00
		$9,311,072 99
It requires for a dividend of 1¼ per cent. on capital stock issued, about		1,191,945 00
Deducting which leaves a surplus, after paying dividend, of		$8,119,127 99

In view of the preceding statements, the Committee recommend that a dividend of 1¼ per cent. on the capital stock of this Company be declared payable on and after the 15th instant.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 921. [Vol. XXXVI. No. 11.] FRIDAY, JANUARY 10, 1896. PRICE SIXPENCE.

NOTES.

THE concise compendium of the law relating to the auditing of companies' accounts, which Mr. SYDNEY MORSE has been good enough to throw into the form of a circular-letter to the electrical Press, is an illustration of the complicated tangle into which the law on a very simple matter is allowed to drift in this country. Instead of dealing once and for all with the important subject of auditing in a single clause in a general Act, the law of audit has to be dug out of half-a-dozen different Acts passed in as many different years. It will be news to most of our readers that an audit is not made obligatory by Act of Parliament in the case of ordinary limited liability concerns; and equally surprising are the wide powers given to auditors under the Metropolis Water Act of 1871. There can be no doubt, after the recent pronouncement by the Board of Trade and Mr. MORSE's clear statement, that the Board of Trade audit has a different object in view to the assumed object of the shareholders' audit. That is in itself, however, no reason why, under a sensible dispensation, a company carrying on such a comparatively simple business as electricity supply should be saddled with the expense and trouble of a double audit.

THE invention of a new name is most meritorious when the new-born name covers an area of thought which can only otherwise be expressed by a cumbersome phrase, and the meritoriousness of the deed is the greater the more frequently the expression has to be used. In any case it is a purer and more dignified process, provided the laws of philology are not violated, than the contraction of the phrase itself into a series of initials, such as E.M.F. or R.M.S. Prof. FLEMING's article this week, on "The Form Factor of Alternating Current Curves," affords instances of both methods. In the term "form factor" which he uses, we have a convenient expression for a ratio, the importance of which in matters relating to alternating current machinery is on the increase. Arising out of a dispute in regard to the value of a sine wave of electromotive force or current in an alternator, there has recently been conducted in all parts of the world a large amount of research on the advantages and disadvantages of different wave forms, and it will be found convenient to have a name such a "form factor," by which an important characteristic of the wave shape may be specified. Dr. FLEMING is inclined to think that the hysteresis loss in a transformer will be constant for different waves having identical "form factors." It is not quite evident that this would be the case. We should have thought that the superposition of one or more rapid harmonics upon the main wave, for example, might considerably affect the hysteresis without causing any change in the ratio of the root-mean-square value to the true-mean value.

IN his article on "Electric Tramways and Telephonic Disturbances" in the current issue, Dr. DU RICHE PRELLER sums up strongly in favour of the "bar" or "shoe" contact for electric traction purposes. It must be admitted that Dr. PRELLER's experience has been such as to lead any impartially-minded individual to condemn the "trolley" wherever telephonic disturbances are to be feared. From the æsthetic point of view the demerits of the "bar" and "trolley" methods are about equal, the former involves the uglier car, the latter the uglier overhead construction.

A SENSATIONALLY-WORDED story has come to hand from Vienna, *viâ* the columns of last Wednesday's *Standard*. It seems that Prof. RÖNTGEN, of Würzburg University, while experimenting with some cloth-screened vacuum tubes in a dark room, in which some sensitised paper happened to be lying about, found that the paper became acted upon by electromagnetic waves. Further investigation enabled Prof. RÖNTGEN to obtain a "photograph of a human hand, showing only the bones and the rings on the fingers," the hand being laid upon a wooden case containing photographic paper, so as to intercept the passage of the rays. The whole phenomenon seems likely to admit of ready explanation, when the conditions of the experiments are more fully published. We cannot, however, agree with the newspapers in regarding this discovery as "a revolution in photography"; there are very few persons who would care to sit for a portrait which would show "only the bones and the rings on the fingers."

A FATAL boiler explosion some time ago, at a station of the Philadelphia Edison Electric Light Company, has led to an inquiry which throws an interesting light upon the boiler practice at that station. The particular steam generator which blew off one of its headers, fracturing the bolts without the least contraction at the fracture, was of the Root type, a well-known form of water-tube boiler. The absence of the

Digitized by Google

usual stretching and contraction of section of the bolts before the explosion led to a suspicion of crystalline structure; but this charge on the part of the electric light company was rebutted by the manufacturers, who showed that the fragments of the bolts were normally malleable and free from brittleness due to crystallisation. How, then, to account for the extraordinary mode of fracture was the problem; but the manufacturers were successful in solving it, and in doing so they turned the tables upon their adversaries. The explosion was due to nothing else than "water hammer," brought about by forcing the boilers beyond their rated capacity some 100 per cent. The manufacturers regarded this practice as "unreasonable handling," showed that "the employés had instructions to keep steam up to the required pressure, irrespective of any demands that might be made on the boilers," and acoused the electric light company of using a forced draught of three or four inches of water when forcing the boilers, as alleged.

PROBABLY most electrical engineers will disagree with the manufacturers of this Root boiler, in believing it to be a sin to keep up the pressure whatever the load. Surely it is a greater error to instal a boiler plant of such a character that to keep up the pressure under a heavy load is either impossible or dangerous. What, too, is to be thought of the design and rating of a boiler plant, in which a draught of four inches is required to force the boiler only 100 per cent.? Lancashire and similar boilers are much more readily forced to this extent, and will work satisfactorily at this rate for a considerable time and without any risk of explosion from "water hammer." It is indeed one of the defects of certain water-tube boilers that they cannot be forced to any considerable extent without the continuity of the circulation breaking down, the tubes becoming filled with steam, often with disastrous results.

WE are often reproached by our implacable friends across the Atlantic for the painfully slow way in which we English are admitting the trolley within our borders. An article on "Track and Overhead Department Economics," in a recent issue of the *Street Railway Review* of Chicago, affords, however, some much-needed consolation to us. Says the author in his opening flourish:—"The alleged 'mistakes of Moses' were few compared to those which have been made in track and overhead construction during the brief period which has elapsed since the advent of the trolley; and the alleged 'wealth of Crœsus' dwindles into insignificance when compared to the vast sums which have been expended in trying to rectify those mistakes." Well, we in England cannot afford to make the "alleged mistakes of Moses," nor do we care to dissipate the "alleged wealth of Crœsus," so long as it is our own wealth; perhaps if it were mostly borrowed from American capitalists we should not mind so very much.

Ayr.—The Ayr central station was formally opened by Lord Kelvin on Wednesday.

Electric Lighting in Government Workshops.—Orders have been given for lighting the workshops in Portsmouth Dockyard throughout by electricity.

Exhibition in Turin in 1898.—A large exhibition is to be held at Turin in 1898, and the Committee of the Electrical Section has just decided that that section shall partake of an international character.

Electric Supply Station Map.—We publish this week a coloured map showing the towns in the United Kingdom possessing the boon of the electric light, and the system and and ownership of each central station.

Cable Interruptions and Repairs:—

	Date of Interruptions.	Date of Repairs.
Aden—Zanzibar	December 24, 1895 ...	January 4, 1896
Puerto Plata—Martinique ...	December 19, 1895 ...	—
Perim—Obock	January 2, 1896 ...	—

House-to-House Oil Mains.—A company is being formed in Lincoln, U.S.A., for the purpose of supplying kerosene through pipes for domestic lighting and other uses. The *Electrical Engineer* of New York calls this "the new process which will render explosions or fires cheap and easy."

Interurban Electric Traction in Germany.—The construction of an electric tramway between Halle and Leipzig (21 miles) is contemplated. Work is about to be commenced on the construction of an electric tramway between Eisenach and Marienthal, the necessary permission having been secured.

A Big Gas Engine and Dynamo Set.—The largest gas engine in Germany, direct-coupled to a dynamo, is now being used in the Lübeck Exhibition for, as the *Gas World* puts it with unconscious humour, "the production of the necessary electric current" for lighting purposes. The engine is rated at 200 H.P., and it is of the Körting type.

A Wide-reaching Patent.—Mr. J. Swinburne, says *l'Electricien*, has just applied for a patent with the following comprehensive ambit: "Improvements connected with electric telegraphs, organs, condensers, deposition of nickel and cobalt, and with packing eggs and other fragile articles, and coating eyelets and such objects, and making bleaching powder."

Appointment.—Mr. Alfred Hay, B Sc., recently demonstrator in electrical engineering at University College, Nottingham, has been appointed as lecturer on electrotechnics at University College, Liverpool, *vice* Mr. F. G. Baily, who has gone to Heriot-Watt College, Edinburgh, as successor to Dr. Mullineux Walmsley. Mr. Hay was in the Faraday Electrical Works (Glasgow) for three years and studied physics under Prof. Tait with distinction, taking first prize in advanced class.

An Electrical Disturbance at Huddersfield.—"There was a rather alarming display of electrical energy at the bottom of Cloth Hall-street, New-street, Huddersfield, on Saturday morning," says the *Bradford Observer*. "Horses passing over the crossing were visibly affected by electric shocks owing to an escape of electricity from the Corporation mains. The charged spot was fenced round, and men were set to work to stop the leakage. Nobody was hurt."

Death from Electric Shock.—At the Eichdorf-Grünberg power transmission plant in Silesia a workman, while trying to do some repairs to a pole carrying the bare conductors, touched one of them with his head and received a 10,000-volt shock. He fell to the ground and died immediately. He had taken up his position on an insulator of the telephone circuit immediately below the power circuit, and was in the act of tying himself to the post. There were burns on his neck and feet marking the entrance and exit of the current.

Electric Traction in America.—About the middle of last month a new Sprague Electric Railway Company was incorporated in the United States, with a capital of £200,000, for the purpose of taking up the problem of electric traction as applied to such systems as the New York Elevated Railways. The new Company is, we believe, under the management of Mr. F. J. Sprague. Interest is being expressed in electrical circles in America in this new venture, and speculation is being made in regard to the type of railway system which Mr. Sprague will adopt. The *Electrical Engineer* of New York, in a leading article on the subject, observes that in the past Mr. Sprague has favoured "the unit motor car as opposed to the train locomotive."

Military Telegraphy.—A *Times* correspondent, in the course of an account of the organisation of the Hungarian cavalry,

Digitized by Google

states that each regiment has a telegraph patrol, consisting of two non-commissioned officers who have undergone a six months' special course of training and of two privates as artificers, forming part of its staff. They carry wire for some eight miles of telegraph and telephone communication, as well as various appliances for re-establishing or for destroying telegraphs and for tapping existing wires. Besides these, each cavalry division would be accompanied on active service by a telegraph detachment, with six four-horse waggons, supplying materials and wire for 20 miles of telegraph and telephone.

English Apathy towards the Polyphase System.—So far as power transmission is concerned, says the *Electrical Engineer* of New York, "the dearth of water powers in England may, perhaps, largely account for the neglect of the polyphase current, at least in its relation to long distance transmission, but aside from this we notice an unmistakable tendency among English electrical engineers to the stretching of the continuous current to its ultimate limit for distribution. Perhaps Lord Kelvin's undisguised antipathy for the alternating current may also have its influence here. But that the polyphase current has come to stay and to grow in usefulness no one who follows the signs of the times will, we think, be prepared to deny, even in England."

Ventilation for Telephone Exchanges.—*Nature* states that an ingenious system of purifying atmosphere and regulating temperature is in operation for the switchboard room of the Chicago Telephone Company, where dust formerly interfered seriously with the connections on the switchboard. The air for the room is forced through a chamber, where it is thoroughly sprayed, then passed through rapidly-rotating spiral coils, which strip it of superfluous moisture, and afterwards through a chamber kept at nearly uniform temperature by the use of ice or heating apparatus, as may be required. Access to the switchboard room is through an ante-chamber, and the temperature of the room itself shows a variation of not more than 2deg. in a month.

The Laval Steam Turbine in America.—It is stated that in a few weeks the Edison Electric Illuminating Company of New York will have in operation at one of their stations two 300 H.P. De Laval steam turbines with attached dynamos. These turbines were built by the Maison Breguet, Paris, and are now on their way to America. They were ordered under guarantee to comply with the following specifications: Each 300 H.P. turbine is to drive two Desroziers dynamos, each of 133 H.P. capacity. The turbine shaft is to run at 13,000 revolutions, driving at a speed of 1,300 revolutions, by means of helical gearing, two dynamo shafts situated on either side of the turbine shaft. Each dynamo is to be capable of generating continuously without undue heating 770 amperes at 130 volts, or 625 amperes at 160 volts.

Electric Tramway for the Berlin Exhibition 1896.—The details of this tramway are now settled, and the line is to be on the circular system, about 2·5 miles long, and will connect all the principal points of the Exhibition. There will be 10 stations. The line will be standard gauge, and overhead conductors will be employed. There will be always on the line 18 trains of two cars each, running at a speed of nine miles an hour, with an interval of 1½ minutes. The fare will be uniform at 1½d. any distance. The cars will be partly of the open and partly of the closed type, and similar to street cars, but more comfortably fitted. Each train of two cars can carry 90 passengers. The line will run along the footpath of the Exhibition, but will be fenced off for the safety of the public. At crossings the line will be bridged over. Naglo Bros., of Berlin, are the contractors.

Electrically Operated Gatling Gun in America.—The Naval Rapid Fire Gun Board has submitted to the chief of the Bureau of Ordnance a report on the trial of an improved Gatling gun. A novel electrical attachment is used with the gun, which permits of about 1,800 shots a minute being fired. The motor is attached to the breech of the gun-casing by an interrupted screw. The electric current is regulated by a switch, and the connection with the firing mechanism made and broken by a push-button held in the gunner's hand. The weight of the motor and casing is 106lb; the length, 21⅜in. The additional length of the gun when the motor is attached is 20in. The projection of the central shaft from the breech when the motor is unshipped is $2\frac{7}{16}$in. The Board says, according to the *Western Electrician* of Chicago, that several hundred shots were fired, the only interruption being due to temporary jams in the gun or feed strips, and that the action of the motor was smooth and regular throughout.

Accumulator Cars at Hanover.—Frequent mention has been made of late of these cars in connection with accumulator traction, but the fact of the matter is that the cars are really worked on a combination system—that is to say, they run on the overhead trolley system while outside Hanover, during which time the accumulators are charged *in situ* on the car, and run by accumulators only when in the centre of the town. The length of trolley line is about ten miles and of ordinary line for accumulator traction about five miles. So far, 32 cars have been equipped with accumulators, but this figure will have increased to 62 by the spring. The accumulators of each car weigh 2½ tons, and the car complete, but without passengers, 7½ tons. The cells are of the Hagen Company's type, the positive plates of which are not pasted. The Tramway Company, so far, has not taken any risk with regard to the cells, but is paying £80 per car per year to the Hagen Accumulator Company for working and maintenance.

Proposed New Anglo-German Cable.—Owing to increased traffic the existing telegraph lines between England and Germany have proved insufficient for some time past, and especially so during certain hours of the day. Experiments have been made on the circuit between London and Emden and on the circuit between London and Hamburg with the Hughes duplex, which has already been tried on shorter cables in this country, with the view of ascertaining whether this system would meet requirements. The first results on the London-Emden circuit were very encouraging, but later on it was found impossible to obtain satisfactory working even though the most skilled operators were employed. Further experiments gave the same results, and the failure was put down to the varying electrical conditions of the Anglo-German circuits which they are subject to, since they are connected to considerable lengths of iron overhead line. It is therefore intended, says the *Elektrotechnische Zeitschrift*, to meet the increased traffic by laying a new cable and erecting copper wires.

Farewell Dinner to Mr. A. P. Trotter.—On Monday evening last Mr. Trotter was entertained at a farewell dinner at the Whitehall Club, and was presented with a gold watch as a small memento of his many electrical friends in the Mother Country. Dr. John Hopkinson was in the chair, and amongst those present were Mr. Preece, Mr. Crompton, Prof. Hughes, Prof. Forbes, Mr. F. H. Webb, Mr. R. P. Sellon, Mr. Garcke, Prof. Grylls Adams, Mr. Mordey, Mr. Swinburne, Mr. Beaumont, Mr. A. E. Mavor, Mr. L. W. Holmes, Mr. H. E. Harrison, Mr. Rawortb, Mr. Bertram Blount, Mr. Henry Edmunds, Mr. Campbell-Swinton, Mr. R. S. Erskine, Mr. G. L. Addenbrooke, and Mr. A. H. Preece. Expressions of regret at inability to attend were also received from Sir Thomas Blomefield, Sir Frederick Bramwell, Lord Kelvin, Prof. Ayrton, Prof. Kennedy, Major Cardew, Major-General Webber and Sir David Salomons and some twenty other gentlemen. "Success to Mr. Trotter" was proposed by the Chairman, and "Electrical Engineering in South Africa" by Mr. Crompton. Other toasts and speeches followed. Mr. Trotter sails for the Cape tomorrow in the Union liner s.s. "Gaul."

Calcium Carbide.—At the annual meeting of the German Electro-Chemical Society, says the *Engineer*, Dr. Borchers exhibited an apparatus by which he not only succeeded, nearly ten years ago, in preparing calcium carbide, but also showed that all the oxides which were regarded as irreducible could easily be reduced by the action of carbon. It consists of a small chamber or furnace of fire-brick, through the walls of which pass thick carbon rods 40mm. in diameter. Inside the chamber these are connected by a thinner carbon rod, 4mm. in diameter and 40mm. long. The furnace is fed with a mixture of lime and carbon. The action is not electrolytic, the effect of the current being simply to heat the lime to a temperature at which it is reduced by the carbon. An electromotive force

Digitized by Google

of 12 volts and a current of 90 amperes is used. The current may be either direct or alternating, and by diminishing the length of the thinner rod calcium carbide can be produced with an electromotive force of only 1 volt, so that electrolysis is out of the question. It was at first thought that alcohol and potassium cyanide might be manufactured cheaply from calcium carbide, but at present there seems little likelihood of these expectations being realised.

"Terrestrial Magnetism."—A new periodical, entitled *Terrestrial Magnetism*, will appear in America this month. It is an international quarterly journal, to be published under the auspices of the Ryerson Physical Laboratory, University of Chicago, and edited by Dr. L. A. Bauer, with the co-operation of numerous workers in terrestrial physics in many parts of the world. The journal, says *Nature*, will be devoted exclusively to terrestrial magnetism and its allied subjects, such as earth currents, auroras, atmospheric electricity, &c. The magnetic needle has become such a promising instrument of research, not only in terrestrial but also in cosmical physics, that the journal which is to be devoted to phenomena connected with it will appeal to a large class of investigators. To quote from the circular heralding the new publication: "No other mechanical means is so surely and so completely recording the physical history of terrestrial and cosmical changes as the self-registering magnetographs of our magnetic observatories, whereby the fitful tremors of the delicately-suspended magnetic needle are being indelibly fixed on the sensitised sheet. On that paper, as Maxwell eloquently expressed it, the never-resting heart of the earth is now tracing in telegraphic symbols, which will one day be interpreted, a record of its pulsations and its flutterings, as well as of that slow but mighty working [the secular variation] which warns us that we must not suppose that the inner history of our planet is ended."

An Electrically Driven Shear.—Ordinarily speaking, the work of driving a ponderous shear is least adapted to the electric motor, as, from the nature of things, the forces which must be applied are not such as can economically be developed directly by the motor. By the aid of a heavy fly wheel and intermediate gearing, however, the difficulty may be overcome. As an example, we may cite the large shear just built for an American steel works in Illinois, where, since all the other plants are electrically driven, it became necessary to drive the shears in similar manner. The motor, according to the *Iron Age*, is a slow speed, steel frame, constant speed machine. The armature makes but 500 revolutions per minute, and is controlled by an extra heavy rheostat that will admit of starting the motor very slowly. This is a very important feature, because the inertia of the flywheel, gear wheel and lever of the shear require great power to start them. The shear itself is the heaviest of its kind, weighing, with the motor, over 90,000 pounds, and is calculated to exert a pressure of 900 tons at the centre of the knives. It has capacity to cut 4½in. square soft steel billets, and as large a section of rounds as is now used in railroad axles. The knives are 18in. long and may be extended to 24in.; are 7in. deep and 2½in. thick. The bed is massive and intended to absorb the great shocks due to heavy cutting. It alone weighs 44,000lb. The cutting edge of the knives is exactly central between the housings, thus throwing an equal strain on both housings. The lever is 14in. through the knife seat, to insure great strength sideways, to resist the cross strain when the knives are dull.

Electric Fuse-Train.—"To Edwin Gomez, of New York," says *Electricity* of New York, "belongs the credit of being the first inventor to enter the electrical field with death-dealing devices, which may be used in sinking English ironclads or in the more peaceful art of blasting rocks. The invention of Mr. Gomez is called the "Electric Fuse Train," and its object "is to effectually retain the force of exploding gunpowder, so that none of it is lost, but simply directing its force to any desired point." The circular announcing this discovery to a war-talking world does not give a detailed description of the invention, but states that the Electric Fuse Train "burns with a sudden and an irresistible flash, the flame and explosion travelling with so great a velocity that it can never be put out by the pressure of water when submerged; and when the flame reaches the torpedo, shell, mine, &c., the coil of fuse train, flashing off, fills the powder-chamber instantly with an intensely hot, confined flame that penetrates the powder and causes every grain to explode at the same instant." By employing this apparatus in igniting gunpowder or other explosives, "an entire revolution may be produced" and "results never before attained may be accomplished, because all the grains of powder are fired at the same time, in consequence of the fuse train being coiled all through the powder, and producing a sufficient flash to penetrate and fill the spaces between the grains of powder in every portion of the powder-chamber. This fuse train is perfectly reliable and excels every other means of communicating fire to one or more charges of powder, torpedoes, shells, mines, blasts, &c., either near together or distant from each other—one line of the fuse train only being required for any number of explosions."

The Leeds Electric Traction Proposals.—At the last meeting of the Leeds Tramways Committee, the members were informed that the report of Dr. Hopkinson upon the experiment in electric traction proposed to be tried in the city had arrived. It will be remembered that at a meeting of the last Highways Committee on October 31st it was resolved "that the necessary steps be taken for the extension of the Roundhay tramway to the Canal Gardens at the Park; that the overhead electric traction system be continued from the junction of the Roundhay tramway at Sheepscar along North-street and Briggate; that in Boar-lane, from Briggate to the Yorkshire Banking Company's premises, an installation of the conduit system be laid; that the overhead system be then continued along Wellington-street and Kirkstall-road to Kirkstall Abbey, and that central poles be used wherever practicable." They also decided to engage Dr. John Hopkinson to advise them as to how best this experiment could be carried out. Dr. Hopkinson informs the Committee that the experiment they suggest is quite practicable, and that if a conduit system is desired in Boar-lane, it could be worked in conjunction with the overhead electric wires in Briggate and Wellington-street. He points out, however, that the cars would have to stop at the junction of the overhead system with the electric conduit in order to alter connections. He suggests to the Committee that this could be avoided if they were to adopt, in place of the electrical conduit system, a system similar to the Westinghouse Electric Company's working model tramway at Westminster. As to a question submitted to him as to whether the refuse destructors might be utilised with advantage for generating the electricity required, Dr. Hopkinson advises not, and recommends that all the power required should be obtained from a central electrical generating station. The Committee decided to visit Westminster for the purpose of inspecting the working of the Westinghouse system. The Committee expect to be able to lay a definite scheme before the Council at its next meeting early in February.

Contemporary Electrical Science.—In the *Acta* of Lund University, Nils Grane described a novel method to determine the temperature at which iron becomes non-magnetic. An iron wire is held by an electro-magnet and heated by a current traversing it until it falls off. The temperature is then found by catching it in a calorimeter. He found, naturally, that under the conditions of the test the temperature at which the change takes place is not constant. It increases with the strength of the magnet, varying between 735°C. and 831°C. For nickel the figures are 368°C. and 481°C.—Another interesting Paper, abstracted, like the last, in *Wiedemann's Beiblätter*, No. 11, is due to F. Sauter, of Ulm, and deals with globular lightning. After considering a large number of authenticated cases of this rare form of lightning, he comes to the conclusion that these globes are masses of incandescent gas, which move slowly and often exist for several minutes. They sometimes disappear silently, sometimes with strong detonation and mechanical destruction, accompanied by electric shocks. The reproduction of such phenomena in the laboratory has not up to the present been successfully accomplished, although Planté and von Lepel managed to obtain small globules conveying the discharge between two plates covered with moist tissue paper.

REVIEWS.

Traité Theoretique et Pratique des Moteurs à Gaz et à Pétrole. Tome II. Par Dr. Aimé Witz. (Paris: E. Bernard et Cie. 1895).

The increasing importance which is being attached to the gas engine by electrical engineers should bring into prominence before the electrical profession the able and valuable researches of Dr. Aimé Witz, whose work on subjects connected with the efficiency and economy of gas motors has done much to throw light upon the complex and recondite aspect of these matters. It is to Dr. Witz that we owe, among other things, much of our information regarding the influence of piston speed on the rate of explosion of the gaseous charge in a gas engine; and, upon the extensive and careful series of experiments in this direction which he undertook, he has founded an ingenious—if debatable—theory of the influence of the cylinder walls in delaying the point of maximum pressure, and in modifying the subsequent conditions of pressure throughout the stroke.

But the work before us is something more than an account of Dr. Witz's researches; it is a comprehensive treatise upon the theoretical and practical aspects of gas motors at the present time. With not quite unmixed feelings of pleasure we have to confess that it is far less of a catalogue and far more of a scientific treatise than any corresponding work in the English language. Perhaps we ought to have stated at the outset that this is an extension of the author's original work "Traité des Moteurs à Gaz," which, after the publication of the third edition in 1892, was found not to cover a rapidly-extending subject. Hence the publication of the present work, which embodies the former one and includes much more besides. In addition to the ordinary text, of which there are some 414 pages in nine chapters, one of which is exclusively devoted to petroleum engines, there are four large folding plates, upon which are depicted scale drawings of some modern types of engine. These, together with the numerous illustrations in the text, are usefully selected and well executed.

The chapter on gaseous fuels deals amply with its subject, but suffers—from an international point of view—from the use of H in place of H_2 in the chemical discussions. It is regrettable that some international code of chemical symbols, with their quantitative significances, cannot be agreed upon and be adhered to by every author. This chapter is divided into four sections. The first treats of ordinary town gas, or lighting gas. It would be well if makers and users of gas engines, and those who advertise their performances, were always to take into account Dr. Witz's warning, that town gas not only varies from works to works, but at the same works from day to day—aye, and from hour to hour sometimes. A close comparison between two rival engines would often be invalidated if the facts as to the relative values of the gas they consumed could be known. We are well aware that scientific trials, such as those made in 1888 by the Society of Arts Commission, are accompanied by gas analyses; but the number of commercial trials which are not is well-nigh legion. The remaining three sections of the chapter on gaseous fuels deal with "poor gas," gas producers and petroleum respectively. A table, covering nearly three pages, which states the chief places where Dowson gas producers are in use, seems to us useless padding.

It is in Chapter V., on the "Théorie Expérimentale des Moteurs à Gaz," that Dr. Witz is at his best, and here the reader will probably find the greatest interest. Dr. Witz makes no hesitation about the matter, but plunges at once into the great contention—upon which, as we have already said, he has thrown so much light—as to the cause of the departure of the diagram of pressures, during the working stroke, from that which mathematical theory would dictate; and the consequent phenomenon of after-burning. "Tresca, Schoettler, Steward and Brooks, . . . Ayrton and Perry, . . . Donkin," &c., have advanced contending views; some have thrown the blame on dissociation, some on change of specific heat in the gases, some on the walls of the cylinder. "Lequel avait raison?" asks Dr. Witz. The answer, which he puts into the mouth of Mr. Dugald Clerk, reminds one of the Greeks playing games below the walls of Troy: "Toute le monde et personne"—all have won and all shall have prizes: all the alleged causes intervene in the phenomenon in question.

Dr. Witz, however, seems somewhat disinclined to admit the finality of this answer; and, no doubt, even if Mr. Clerk is right qualitatively, there is still the relative importance of these several influences to be determined. Naturally, Dr. Witz is disposed to attach the greatest importance to the action of the cylinder walls. This has been his special line of research, and by its aid he has obtained light which, apparently, other lines of research in this question have failed to yield so clearly. Yet, as he emphatically states, the theory is even now far from complete; and it is requisite that numerous and systematic trials and tests should be made by various methods under various conditions, and that these should be "discussed, compared, reconciled," before we can expect to see the time when they will establish "la théorie expérimentale sur des bases de granit: c'est une question de temps et de travail." Happily there are many workers in this field.

We have not space to enlarge upon the remaining contents of Dr. Witz's treatise; but what we have said should serve to show that it is a work which ought to be in the hands of everyone who is desirous of studying the modern developments of the gas engine in practice and in theory.

Annuaire pour l'An 1896. Edited by the Bureau des Longitudes. (Gauthier-Villars et Fils.)

The 1896 edition of this compendium of physical, electrical, chemical, astronomical and ethnological tables contains a brief historical summary of the action-at-a-distance and undulatory theories, and a lengthy account of the optical researches of Fresnel, both by M. Cornu; also M. Janssen's account of his third ascent of Mont Blanc, and an interesting biographical notice of the late Rear-Admiral Fleuriais by Captain Bernardières, of the French Navy, who also contributes a short account of the magnetic cartographic work now being carried out under the auspices of the French Government. As the Annuaire contains, in addition to purely scientific data, a mass of information with regard to calendars (Gregorian, Julian, Mohammedan, Jewish and Chinese), tables of foreign money equivalents, compound interest and sinking fund tables, &c., it would be difficult to say who could purchase it without finding something useful therein.

Submarine Telegraphy. James Bell, A.I.E.E., and S. Wilson. (London: "Electricity.")

This purports to be mainly a handbook on submarine telegraphy, and is styled by the authors "A Practical Book for Practical Men." In no wise do its contents justify its title. Barely 11 pages are devoted to submarine telegraphy, and moreover, of these nearly five are taken up with descriptions of an improved siphon recorder and two automatic transmitters, not the best known, perhaps, of their kind. Everywhere in the superficial and scanty information given on submarine cables we find errors and crude statements, manifesting on the part of the authors but slender acquaintance with the subject on which they have set themselves to treat. Of these errors it will suffice to notice one or two. Nearly a page is sacrificed in describing the theory of reflection as applied to the mirror galvanometer, while the "Minotto" cell, we learn, is used to work cables, further space being wasted in describing this bygone means of producing electrical energy on a small scale. The authors also inform us that a current flowing through a siphon recorder coil causes it to vibrate (*sic*). Again, we are told that the Commercial Company's cable system gives a working speed of 60 words a minute by means of the automatic system, which is an impossibility having regard to the length of the cable and its weights of copper and G.P. The method of duplex working shown in Fig. 9 is cumbersome, ineffective, and now obsolete for long cables, by reason, as is well known, of the retardation it introduces in the bridge arms R and R_1. The teredo we find referred to as having only recently been safeguarded against by means of brass tape, though the first brass-taped cable dates several years back, and since then

Digitized by Google

cables innumerable have been similarly protected against the ravages of that genus.

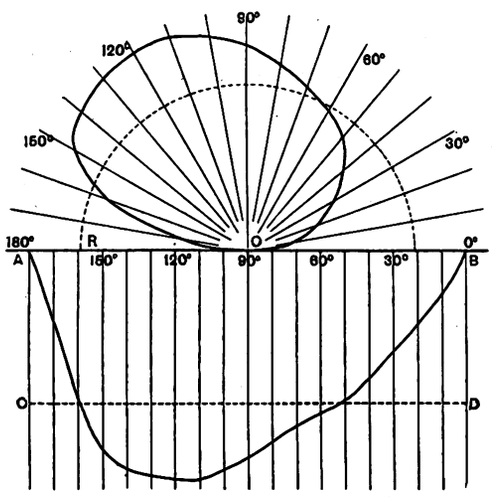
In the three small paragraphs headed "Test for Faults," and amounting in all to 18 lines, the authors surpass even themselves. We quote the first paragraph only—the italics are our own: "When a *disconnection* occurs in a cable, *both offices work with copper currents*, the copper having the effect of sealing up *a fault* by depositing chloride of copper on the *broken ends*, whereas a zinc current would *clean the ends and stop communication*. The copper current, however, gradually eats away the *ends of the conductor* and eventually breaks down communication."

But enough. Should the authors attempt any further "practical book for practical men," let us hope they will first take the trouble to study their subject, and that they will give any such book a less misleading title than their present effort so unfortunately bears.

THE FORM FACTOR OF ALTERNATING-CURRENT CURVES.

BY J. A. FLEMING, D.SC., F.R.S.

In the design of alternators, as well as in the discussion of some transformer problems, we have frequently to consider the relation between the true mean (T.M.) value and the square root of mean-square (R.M.S.) value of the equispaced ordinates of a single-valued curve representing a periodic current or electro-motive force. It is convenient to have a simple term to express this ratio. I venture to suggest the term *form factor* for it. This quantity has been already recognised and symbolised in various alternating-current investigations by Mr. Kapp, Dr. Roessler and others, who have pointed out its significance. If f stands for the form factor of any periodic curve, then $f = \frac{\text{R.M.S. value}}{\text{T.M. value}}$ of the ordinates of a semi-wave taken at equidistant intervals along the time axis. If y is the ordinate of the curve and x is the half-wave length, then $f = \frac{\frac{1}{x}\int_0^x y^2\,dx}{\frac{1}{x}\int_0^x y\,dx}$. Geometrically it can be obtained as follows: On any horizontal line draw a wave diagram to represent the half-wave of a periodic curve of electromotive



force or current, and with any point on this line as a polar centre draw a polar diagram to represent the same curve. With the planimeter find the areas of each of these curves and find the rectangle equal in area to the wave curve and the semicircle equal in area to the polar curve. Then the ratio of radius O R of the semicircle to the altitude B D of the rectangle is the form factor for the curve considered. For it has been shown that the radius of the semicircle represents the R.M.S. value of the ordinates of the curve, and the altitude of the rectangle represents the T.M. value of the same.

The form factors for certain curves are given below:—

Curve.	T.M. value of ordinate as fraction of max. ordinate.	R.M.S. value of ordinate as fraction of max. ordinate.	Formfactor f.
Sine	0·637	0·707	1·1
Semicircle.....	0·7854	0·835	1·063
Triangle	0·5	0·58	1·16
Rectangle.....	1·0	1·0	1·0
Semi-ellipse.....	0·785	0·816	1·039
Parabola with axis vertical.....	0·666	0·730	1·096
Two semi-parabolas meeting at a cusp..	0·33	0·447	1·35

The more peaked the curve the larger the form factor. If one dared to disregard proprieties of language, the form factor might otherwise be called the "coefficient of peakiness" of the curve.

It is now well understood that the core loss in a transformer depends upon the form factor of the curve of primary electromotive force, and that an increase of form factor causes a diminution of core loss due to hysteresis. It has not yet been entirely demonstrated that curves of electromotive force of different shape but equal form factor will give equal hysteresis loss, but it is very probable such would be the case. Under these circumstances a specification for transformers is incomplete unless it is stated that the test of core loss shall be made on an alternator with a curve of electromotive force having a given form factor. The form factor of the curve of electromotive force of an alternator may change considerably as the character of the load whether inductive or non-inductive is altered, if the alternator is one having a large armature reaction.

ELECTRIC TRAMWAYS AND TELEPHONIC DISTURBANCES.

BY C. S. DU RICHE PRELLER.

Introduction.—In the course of last summer the writer took the opportunity of investigating the effects of the working of certain electric tramways on telephones in Switzerland, Alsace, and France, more especially with the view of determining (1) which of the different overhead contact systems is most liable to cause telephonic disturbances, and (2) whether the disturbances, if any, are due to induction, leakage, or to other causes.

It is, of course, not the purpose of this Note to enter into a detailed description of the various electric tramways examined; suffice it, therefore, to briefly state the features which bear strictly on the subject under notice, in reference more especially to the tramways of Zurich, Geneva, Bâle, Mulhouse, Havre and Marseilles.*

Contact Systems.—The three (now four) electric tramways so far constructed in Zurich all radiate from one central point near the lake, and connect various suburbs on the hills flanking the town, the aggregate length being about six miles, worked on the trolley system. At Geneva, where the entire system of horse tramways is now being converted to electric traction, the first section, connecting one of the suburbs with the centre of the town, is about four miles in length, and is worked with a slide contact shoe, which system will also be used on the extensions. The tramway at Bâle, traversing the town from one end to the other, and crossing the Rhine about midway, is three miles in length, and is worked on Siemens and Halske's contact-arm, or, as it may not improperly be termed, "cross-bow" system. This contact will also be used on the other lines to be constructed further on. Precisely the same remarks apply to the tramways of the neighbouring town of Mulhouse (Alsace), where steam traction is being replaced by the system just

* A detailed account of the Marseilles and St. Louis Tramway by the writer was published in *Engineering*, 1893.

Digitized by Google

mentioned, and the lines so far converted measure about five miles in length. The Havre network of electric tramways, comprising at present 12 miles of chiefly double line, is worked on the trolley system, which is also in operation on the Marseilles and St. Louis tramroad, three miles in length. It may be added that on all the lines mentioned the steepest gradient is 5 per cent., at Zurich and Marseilles 6·5 per cent. (1 in 20 and 1 in 15 respectively), and the minimum radius of curvature is in all cases 20 metres, or 66 feet.

Insulation.—The means of ensuring the continuity of the return circuit through the permanent way are, in all the cases referred to, substantially those now commonly adopted, that is, the girder rails are bonded at the joints by 8mm. to 10mm. copper wires fastened through, and soldered to the web, the wires being connected at equal distances, varying from 30 to 100 metres (100ft. to 330ft.), to an uninsulated copper conductor of the same diameter, which is laid between the rails throughout the whole length of the line. The only exception is the line at Marseilles, where the conductor is a lead-covered galvanised iron wire.

The means of insulating the contact wire, too, are very similar in all cases—that is, where span wires and iron posts are used, threefold insulation is provided (*a*) between the contact wire and the span wire at the point of suspension, (*b*) between the span wire and the collar resting on the cap of the post, and (*c*) between the cap and the post.

Telephones.—On examining the arrangement of the telephone lines in relation to the electric tramways referred to, the writer found that at Zurich the telephone wires are, along one section of tramway, laid underground in iron pipes, whilst along the remaining sections, which form by far the greater part of the entire length, the wires are carried overhead, and that, although at certain points they cross the contact wire of the trolley lines more or less at right angles, there are various sections up to 200 metres (660ft.) in length each, where from 40 to 80 telephone wires, not provided with metallic return, run parallel, or nearly so, to the tramways at a vertical or horizontal distance varying from 1 to 5 metres (3·3ft. to about 16ft.). Similarly, at Geneva, the telephone wires are, to a small extent, laid underground, but for considerable distances along the tramway, and in sections up to 600 metres (660 yards), they are carried overhead, the distance from the tramway line being in some cases 5, in others only 1 to 2 metres (about 16ft., 6ft., and 3ft.), and the telephone having earth return. Again, at Bâle, and also at Mulhouse, overhead telephone wires with earth return run for long distances parallel to the tramway, and are from 12 to 15 metres (40ft. to 50ft.) apart from the latter. At Havre, and likewise at Marseilles, the telephone wires running parallel to the tramways are placed at a distance of 15 metres (50ft.) from the latter, and are provided with metallic return.

Disturbances.—The tests made by the writer of the telephones at Zurich showed that in all the districts traversed by the electric tramways there are serious disturbances, the starting and stopping of the cars, their passage through curves, the action of the motors, and notably the "singing" of the armatures, being so distinctly audible as to materially interfere with telephonic communication. In a minor degree these disturbances extend all over the town, the writer himself having traced them to within about two miles from the nearest tramway line. The inconvenience thus caused in the more immediate neighbourhood of the tramways is so great that the overhead telephone wires most affected are now being laid underground. At Geneva, as well as at Bâle and Mulhouse, the writer found, in striking contrast to Zurich, that even at the public or private telephone stations in close proximity to the tramways, the disturbances are so insignificant as to be practically *nil*, an observation which is, moreover, confirmed by the fact that in neither of these towns has the working of the electric tramways given rise to any complaint, and consequently no remedial measures, such as those at Zurich, have been necessary. On the other hand, at Marseilles, as the writer pointed out at the time (1893), considerable trouble was at first experienced in connection with the telephones, the disturbances being very similar to those observed at Zurich, and the public or private telephone stations more especially affected being those situated in houses to which span wires of the tramway line were attached, at a distance, in some cases, of only about 3ft. from the telephone wires. An experimental remedy to protect the telephones by means of induction coils and condensers proved of little or no avail, and telephonic communication continued so unsatisfactory that the telephone wires most affected were in the end removed to a distance of 15 metres (50ft.) from the tramway, and provided with metallic return. Again, at Havre, the writer found that the electric tramways, after being opened for traffic, gave rise to complaints, albeit in a much less degree than at Marseilles and Zurich, the telephonic disturbance being restricted almost entirely to the sound produced by the starting of the cars. Here, too, however, the telephone wires, placed at a distance of 15 metres (50ft.) from the nearest tramway line, had, by order of the authorities, to be doubled, the metallic return being extended to the entire telephone system of the town.

Causes.—The broad and striking result of the investigations thus made by the writer is that the electric tramways of Zurich, Marseilles, and Havre, worked on the overhead trolley system, have given rise to more or less serious telephonic disturbances, which necessitated remedial measures, whilst the tramways of Geneva, Bâle, and Mulhouse, worked with an overhead slide contact, have produced no such disturbances. The phenomenon is at first sight puzzling, and it will be interesting to briefly examine its causes.

To some extent electromagnetic and electric induction must, of course, always take place between two sets of parallel overhead conductors, such as tramway contact wires and telephone wires, the principal cause being the extreme sensitiveness of the latter, in which consequently even very slight inductive effects of the higher tension current* are reproduced. In the cases under notice, where the two sets of conductors are carried on, or suspended from, separate supports, the magnitude of the disturbances depends, in the main, on the magnitude and suddenness of the changes of the inducing current and its pressure, on the length over which the two sets of conductors run parallel, and on the distance between them, the inductive effect being, however, by no means in a simple ratio to that distance. Both at Zurich and Geneva the safeguards against excessive induction are practically the same—viz., the two sets of conductors cross each other at certain intervals, and the tramway working current, being the higher tension current of the two, has a separate return by means of the conductor between the rails, while, on empirical grounds, the large number of telephone wires tends *per se* to lessen the effects of induction. Notwithstanding this equality of conditions—those at Geneva being, indeed, more unfavourable owing to the greater parallel lengths, and consequently the considerably higher coefficient of induction†—there are serious telephonic disturbances at Zurich, whilst at Geneva the disturbances are inappreciable or *nil*; hence it is reasonable to conclude that the phenomenon in the former town is not primarily, and certainly not entirely, due to induction.

It has already been shown that the ordinary means adopted for minimising leakage are practically the same in all the cases referred to. It might be argued that the morainic soil of Zurich is more conducive to earth currents than the gravel soil of such towns as Geneva and Bâle; but this argument would possess some value only in the case of clay or other soil which, being impervious, retains moisture.

The primary cause of the telephonic disturbances must, in the writer's opinion, be sought in the trolley system itself. There is, in the first place, between the two systems of trolley and slide contact a marked difference in the mode of suspension; for while the trolley contact wire requires a large number of points of suspension, especially in curves, so as to conform to the axis of the tramway, the conductor for slide contact bars or cross-bars can be laid out in long polygonal sides with very few points of suspension, and at crossings the contact wires are

* It is hardly necessary to state that the pressure of the working current is in all cases 500 to 600 volts.

† The coefficient of reciprocal electromagnetic induction is $= \frac{2l}{10^9}$ (log nat $\frac{2l}{d} - 1$), l being the parallel length and d the distance apart, in centimetres.

Digitized by Google

simply soldered together, thus ensuring continuity of contact. In the trolley system, on the other hand, every point of suspension, whether it be an ear clamping the contact wire or a frog at crossings and bifurcations, involves a jump of the trolley wheel over the obstruction in the former and over the gap in the latter case, and this necessarily causes sparking, which *e.g.*, at Zurich is particularly violent, and occurs at almost every point of suspension. Consequently, leakage takes place through defective contact, and it is this latter which, in the writer's opinion, constitutes the primary cause of the telephonic disturbances. This view is confirmed by a trial which the writer witnessed on one of the lines at Zurich, when the Geneva slide contact was temporarily substituted for the trolley wheel, with the result that the sparking and the effect on the telephones were practically the same, thus showing that the fault lies not so much in the trolley wheel *per se* as in the overhead system which the trolley wheel involves.

Another cause which tends to intensify the telephonic disturbances referred to must be sought in the construction of the motors as well as of the contact pieces. In this respect the noiseless running and inappreciable wear of the motors and of the chain motion used at Bâle and Mulhouse contrasts strikingly with the howling of the motors and the rattling of the spur gearing on the Zurich lines after little more than 12 months' running, albeit the steep grades and sharp curves in the latter town account, to some extent, for the more rapid wear. No less striking is the contrast between the smooth, silent gliding of the aluminium cross-bow slide in the former towns, and the grating, more especially in curves, of the trolley wheel against the contact wire.* All this "concord of sweet sounds" finds its echo in the telephones as the effect of induction, while the starting of the motors, involving a sudden increase of current, affects the telephones more especially owing to the sudden rise of the difference of potential between earth connections as the effect of defective contact and the inadequacy of the ordinary means of insulation.

Conclusion.—It has been shown that a good slide contact system, in conjunction with well-constructed and smooth-running motors, is much less liable to affect telephones having earth return than the trolley system, which, in the various cases enumerated, has necessitated remedial measures, consisting either in the burying or the doubling of the telephone wires in the vicinity of the electric tramways.* The cost of the former operation was, at Zurich, about £1,600 per mile (25,000fr. per kilometre), of which the tramway companies have so far contributed about half; while at Marseilles the cost of removing to a distance of 15 metres (50ft.), and doubling the telephone wires most affected, was entirely defrayed by the Company, and amounted to £1,000 per mile (about 16,000fr. per kilometre) of tramway; and at Havre, the company had to contribute for the same purpose the sum of £5,000, being at the rate of about £600 per mile of tramway. The average cost is therefore about £1,000 per mile, and this has been entirely saved in the three other cases where the slide contact system has been adopted.

The writer is very far from wishing to disparage the overhead trolley system, which, in its rough and ready fashion, has rendered immense service in the United States, and is well adapted also for suburban and country districts in Europe. But as regards the peculiar conditions of many towns in Europe, and more especially in this country, it may fairly be averred that, if overhead wires are tolerated at all, the slide contact system as already in operation in various Continental cities, *e.g.*, at Dresden, Hanover, Barmen, on the suburban lines of Buda-Pesth, and elsewhere, and in a somewhat different form in the Isle of Man, is free from many of the disadvantages inherent to the trolley system, and therefore marks a conspicuous advance on the latter. More especially is this the case in towns and districts where the risk and responsibility of telegraphic or telephonic disturbances, and not only the considerable cost, but the local difficulties of remedial measures, have to be reckoned with; and it is with the view of drawing attention to this important point that the writer deemed it opportune to give publicity to his impartial investigations in the interest of electric traction.

* This defect has recently been mitigated by substituting for the American trolley wheels with narrow groove, other wheels of better material, and having a groove 4·6cm. (1·8in.) in width, which allows more lateral play. It is not infrequently contended that a contact slide wears the contact wire. This is, however, a fallacy, and, according to the writer's experience, the reverse is the case, viz., the slide contact piece being invariably made of softer material than the contact wire, it is the latter which wears the former. In the aluminium cross-bow used, *e.g.*, at Bâle, the wear is reduced to a minimum, the more so as both the contact surfaces are well greased, the oblong and curvilinear contact frame, 1·5m. (about 5ft.) in length, being self-lubricating. It is, moreover, self-reversing.

* As another case in point may be mentioned the Douglas and Laxey (Isle of Man) tramway, where, as Dr. E. Hopkinson informs the writer, no trouble whatever has been experienced from telephonic disturbances, although the Company's telephone wires are fixed upon the posts of the Government telegraphs at a distance of not more than 25ft. from the tramway conductor, and run parallel with the latter for nearly two miles. The telephone wires have, it is true, metallic return; but, as is well known, even this by no means affords absolute protection against inductive effects such as might be produced within a short distance from the line if the latter were worked on the trolley instead of the slide contact bar system. A further case is that of the Mont Salève electric mountain railway near Geneva (*vide* the writer's account in *Engineering*, 1894). On this line, worked with a slide contact and an outside conductor rail, simple electrical bonding at the rail joints without a separate return conductor sufficed to stop the telephonic and telegraphic disturbances at first experienced, and the doubling of the wires could be dispensed with.

THE "SAFETY" SYSTEM OF CONCENTRIC WIRING.

At a time when the discussion on two Papers on concentric wiring is pending at the Institution of Electrical Engineers, some particulars of the "Safety" system may be of interest. This system of wiring, which has been developed during the last five years under the "Andrews" patents, is designed principally to provide a fire-proof and safe system of interior electric wiring on lines which somewhat resemble those of ordinary gas fitting. The system is concentric, with the outer conductor bare and well earthed; and the conductors and other fittings attaching to it are the manufactures of Messrs. Sharp and Kent. The chief features of the system may be summarised as follows: (1) No wood casing is used; (2) every joint is hermetically sealed, and is thus damp-proof; (3) every connection is made with a screwed coupling similar to a gas fitting; (4) all switches and fuses are enclosed in metallic cases; (5) the external conductor or sheathing and the cases of all the fittings, &c., form a continuous conducting earthed-return circuit.

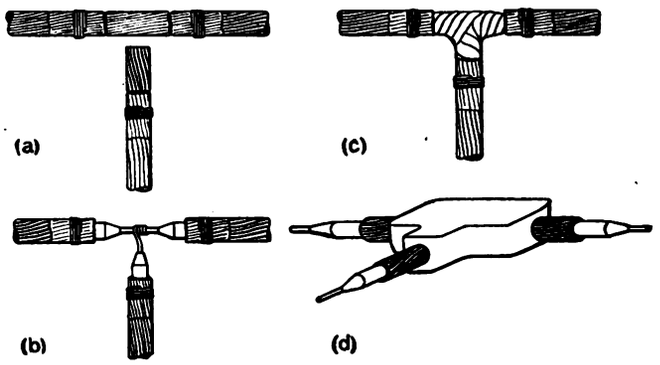


FIG. 1.—Method of making a T joint.

The cable used on the "Safety" system consists of ordinary copper conductor, insulated with vulcanised india-rubber, and surrounded with an armouring of copper or iron wires, this armouring forming the return conductor. The manner of making a joint is interesting, and, in the case of a T joint, is as follows: In Fig. 1, let (*a*) represent the two pieces of concentric cable to be jointed. First the outer sheathings are bound round with thin copper wire, as shown at (*a*), and then tinned. The armouring is now cut away, leaving the insulation projecting, and the inner wires are cleaned and jointed, as shown at (*b*). This inner joint made, it will be insulated with pure rubber, then with a layer of white rubber, followed by vulcanised strip, and finally silesia strip, as shown at (*c*). A copper sheath is now placed over the insulated inner joint, and the ends of the outer

Digitized by Google

sheathing are joined. When this has been done the T must be placed in a mould, shown in Fig, 2, and molten fusible metal must be poured over and around the copper sheathing, the heat of which operation will perfect the vulcanisation of the joint. When this fusible metal is cooled a firm, strong, water-tight and well-insulated joint will have been made, the general appearance of which is seen at (*d*) in Fig. 1. Such a joint as this is usually made, in factory and cheaper classes of work, where a pendent is to be attached to the main conductor; but in better class of work the attachment will be by means of a screw ferrule, as shown in Fig. 3. It may be remarked that the lamps themselves are provided with screw threads which

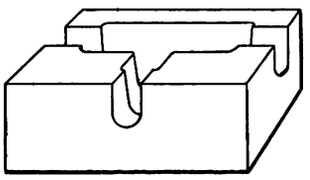

Fig. 2.—Mould for T joint.

will fit the sockets into which the fittings are usually screwed, so that a cheap and expeditious plan is to attach the lamps directly to the sockets without any intermediate fittings.

The "Safety" system of concentric wiring, though mainly designed for interior conductors, is not essentially restricted to this purpose, but can readily be adapted to the requirements of low-pressure street mains and feeders on the two or three-wire system. Indeed, we understand that Messrs. Sharp and Kent have the contract for laying the mains of the three-wire system at Guildford, and will adopt the "Safety" system of conductors in that contract, with only such slight modifica-

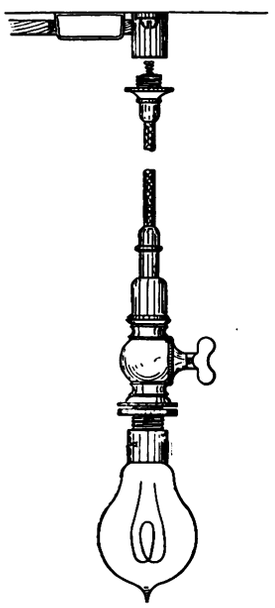

Fig. 3.—Pendant with Screw Ferrule.

tions as are necessary on account of the difference in the conditions. Both for interior and exterior wiring, therefore, the "Safety" system appears to answer its purpose; and in the former class of work it has, we understand, received the approval of the officials of several leading insurance offices.

A STEEL-CASED MOTOR.

The accompanying illustrations show a new design of enclosed type motor constructed by Messrs. Mavor and Coulson under the Sayers patents. The general features of the motor are similar to the enclosed type of machines which this firm have manufactured for some three years past. The enclosing casing is of low carbon steel of high magnetic permeability, and forms a magnetic shell from two opposite points of the inner surface of which the field poles project. Thus, in addition to the enormous protective strength of the steel shell, these machines are practically devoid of external magnetic field, and on this account are well adapted to ship work, the effect on the most delicate compass being, it is said, imperceptible at quite a short distance. Great improvements have recently been made in the general design of these machines.

In regard to the general performance, the following are particulars of test runs of a machine designed to give 12 B.H.P. at 770 revolutions:—

Efficiency Test.—12*in. by* 7½*in. Motor driving Generator by Belt.*

Mean of Three Readings.

Motor.			*Generator.*		
Speed.	Volts.	Current.	Speed.	Volts.	Current.
775 ...	122 ...	104	885 ...	100·8 ...	100·4

Motor input = 122 × 104 = 12,600 watts.
Generator output = 100·8 × 100·4 = 10,170 watts.

$\frac{10,170}{12,630}$ = 80 per cent. efficiency, double conversion.

The motor was run as a generator with a view to ascertaining the rise of temperature for continuous running, as under:—

12*in. by* 7½*in. Motor run as Generator.*

Direction of Rotation—Counter-clockwise.

Time.	Speed.	E.M.F.	Current.	Remarks.
2:30	766	110	89	
2:55	756	111	89	Stopped 10 minutes to repair belt.
3:10	795	110	92	
3:20	790	110	90	
4:0	785	110	88	Brushes sparkless throughout.

4:45	780	110	88	
5:0	784	110	90	
5:15	784	110	88	
5:30	784	110	88	

Maximum Temperatures.

Magnet coils.....	111°F.	..... Rise.....	53°F.
Armature	120°F.	..... „	62°F.
Air	58°F.	.....	

The machine was next run for 6 hours as a generator at 40 per cent. over rated load.

Time.	Speed.	E.M.F.	Current.	Remarks.
10:30	800	110	126	Sparkless.
11:0	800	110	122	„
11:30	810	110	124	„
12:0	830	110	120	„
12:30	840	110	120	„
1:0	840	110	118	„
1:30	845	110	126	„
2:0	850	110	123	„
2:30	855	110	120	„
3:0	860	110	124	„
3:30	865	110	123	„
4:0	865	110	123	„
4:30	860	108	122	„

At end of six-hours run at 40 per cent. over load the following maximum temperatures were observed:—

Armature	144°F.	..... Rise.....	90°F.
Magnets.....	128°F.	..... „	74°F.
Air temperature	54°F.	.....	

A test was made to see what load could be carried without sparking at the brushes, with the following results:—

Time.	Speed.	Volts.	Current.	Remarks.
11:0	Not taken.	100	175	Run for 15min. without any sign of sparking.

A subsequent test showed that slight signs of sparking appear with a load of 185 amperes.

When running as a dynamo the machine was loaded up to 120 amperes; the load was then suddenly reduced to 80

Digitized by Google

amperes, when, without change of position, the brushes remained absolutely sparkless; on reducing the load to 40 amperes only slightest traces of sparking were visible. The rocker was then moved to sparkless position with 40 amperes, and then all load switched off, when the machine remained absolutely sparkless, running light. Copper gauze brushes were used.

The following particulars of this size of machine may be of interest: Weight of machine complete, 16¾cwt.; resistance between brushes at 120°F., 0·0435 ohm; resistance of shunt at 120°F, 53 ohms. A portion of the top part of magnet shell at commutator end is hinged to the main portion, and when opened, as shown in Fig. 2, allows of ready inspection and adjustment of brushes, &c. The top part of shell lifts off vertically, after

ILLUMINATION versus GLARE.*

BY ALBERT SCHEIBLE.

One of the most notable events of the past year was the advent of a practical illuminometer. It was noteworthy not so much because it is more needed to-day than a photometer, but more particularly because it emphasizes illumination as the one thing to be attained by electric lighting. We have learnt to produce light at any desired spot and in any desired unit, and we can now do this at a very low cost considering the methods used. Hence it is high time that we should turn our efforts towards using this light to produce the desired effect. In doing so we must remember that it is not the lamps themselves which we want to show; they are merely accessories—necessary evils, perhaps—and as such we gladly tolerate them as means towards our end. That end is illumination. It may be the illumination of a show window, a store, a parlour, a workshop or a street. In each case there is something other than the lamps which we want to exhibit; the lamps themselves can be quite inconspicuous while still supplying the light for the store display, the reception room or the avenue. I say they can be inconspicuous, though as yet we rarely find them to be so.

Not many years ago, when electric lighting first came into use, the public clamoured for it as something new, something that should not only be used but readily seen as well. It was not enough then for the townspeople to know that so intense a light could be produced in so small a space; they wanted to have this intensity kept prominent—wanted to be dazzled by the penetrating rays even if they were thereby kept from seeing what was supposed to be lit up by the lamps. But that era has now gone by. We need no exhibit of arc or incandescent lights in our stores or streets; what we do need is the light itself. To use this in the most effective manner we need to get rid of that exhibition glare which custom has handed down to us as a dazzler and incidentally as an illuminant. Are we doing so to-day? Just look at a few pert examples.

1. *The Show Window.*—Everybody knows that this is the one place above all others where the dealer wants the public to see his wares. Time and expense are seldom spared in causing these windows to serve their proper object. Models are devised to show the proper use of the goods, and artists are set to work arranging them so that the eye will long to rest upon them; the result is a feast for the passer-by. At least it is so in the daytime, but rarely so at night, and why? Is it for lack of light? Certainly not, for hundreds of candle-power are cast on the window in excess of what it received at noonday. Perhaps there is an arc lamp right in front of the window, or there may be a border of incandescents around the edge. In either case it is the lamps and not the goods that catch and hold your eye. You stop and say to yourself: "Oh! how pretty those lights are!" And you go on, forgetting that there were goods in those show windows, and that the real purpose of the lights lay not in their being pretty themselves, but in showing up a pretty something else. The true beauty of the light—that of its meek utility—had been entirely missed.

Yet things can be otherwise. There are some stores already where the light in or near the windows is concentrated on the goods and shielded from the observer's eye, where the electric light readily produces the desired illumination without reducing the effectiveness of it by the offensive glare. Perhaps we are too strongly prejudiced in favour of the electric lights; then let us look at gas jets or Welsbach burners in similar locations and with all charity for the latter ask ourselves if even the right light in the wrong place (the glaring, self-conspicuous place) is what we want.

2. *In the Home.*—When we place lights of any kind in the rooms of our house we generally look upon them as mere substitutes for the daylight during the hours when this is not available, and we are justified in calling that method of lighting the best which most nearly approaches the diffused daylight in its effect. We need not pretend to imitate the dazzling sunlight, for we carefully exclude its glare by shutters or moderate it by tinted shades. Thanks to these shutters and shades we get a mellow and diffused light, inoffensive to the eyes but ample for giving thorough illumination to the room. When evening comes it would be only natural for us to reproduce this illumination as best we can, and surely the incandescent lamp is the best medium yet devised for producing a close approach to the daylight effect. But where is the residence which can boast of this mellow lighting by night as well as by day? Surely the grouping of a few incandescent lamps where they can glare right into one's eyes cannot give the desired effect any more than we would get it during the day by admitting the bright sunlight through three or four peep-holes. Custom told us to place our incandescents just where we were used to seeing our oil or gas lamps. But these had to be within easy reach as they needed frequent adjustment, and they also had to be kept at a respectful distance from the wall or ceiling to avoid fires. Fortunately the incandescent lamp is not subject to these same ailments, and as the most modern of the lot it surely should not be handicapped by the faults of its predecessors. If we must have the lamp right before our eyes we can frost its bulb and perhaps enclose it in a much larger opalescent globe, so that we will see not a dazzling white horseshoe-shaped filament but a dimly glowing ball of light. I for one like to see the light dimmed and diffused in this way, and I prefer even then to place the lamps close to the ceiling, where they will be least noticed by sensitive eyes. If you can have a number of such glowing globes scattered along the ceiling each with a lamp of rather low candle-power, the result will be so much the better, since it more nearly reproduces the diffused daylight effect.

Perhaps you will ask as to the economy of such a plan: "Will it pay to cut off a third of the light by the tinted globe?" I think it will, for it is not so much the candle-power output of our lights that counts, but rather the illuminating effect produced by them. When we put a 16 c.p. incandescent in place of a 10 c.p. double gas burner or 8 c.p. of oil lamps, we spend more candle-power of light on the room, but do we necessarily get a more effective illumination? Is it not a fact that we strive during the day to keep down the candle-power of light which comes into our rooms, in order that we may have just the amount needed for a proper illumination? Any light in excess of this is injurious to our eyes and detracts from the effect of all the objects when we look at them for any length of time.

If we want to exhibit the lamps themselves we can find many ways of doing this by using the miniature forms now on the

* From the *Electrical Engineer* of New York.

Digitized by Google

market. But for effective and artistic lighting I trust that the time will come when the incandescent lamp will be merely the power behind the globe, from whence it can shed a truly diffused light on our room without being seen of itself.

3. *Street Lighting.*—When we come to the lighting of streets and alleys the question of candle-power is apt to be misleading unless it is kept subsidiary. The fact that lighting contracts, when not made on a midnight or an all-night basis, are usually taken on a moonlight schedule, shows that the illumination due to the moon in its second or half-moon phase is considered ample for lighting the streets at night. Many small towns have tried to reproduce the moonlight effect by using tower lights, but the shadows from two or three-story houses or from trees of almost any size have spoilt the result in most cases. The more common method of using arc lights at every street crossing is certainly far from giving a moonlight effect. It invariably gives an intense illumination to a spot fifty or a hundred feet in diameter, but when you go beyond this area the intense shadows and the dazzling rays detract from the effectiveness of the illumination, thus leaving the street rather poorly lighted for either riding, driving or walking. It is not a lack of light in this case, but a lack of its proper distribution. In the case of incandescent street lighting there are usually three or four lamps to a block, and while the absolute candle-power per block is much lower, the illumination produced may still be much more satisfactory. The light is more evenly distributed in this case, the lamps are near enough to avoid any deep shadows, and the glare of the lights themselves is almost insignificant as compared with that of the arc lamps. This point is noted alike by pedestrians, teamsters, horseback riders or cyclists—in fact by everybody for whose benefit the street is illuminated. The more uniform distribution of the light, together with the absence of the glare and of the intense shadows, all help to bring the incandescent "many-lamps-to-a-block" method much nearer to producing a moonlight or diffused daylight illumination than the usual plan of having arc lights at every corner or at alternate ones. It would, therefore, seem worthy of a great deal more attention than it has heretofore received, and while it may not be universally adaptable, still for most places a street hood incandescent method should give the most desirable and effective illumination.

I have mentioned just three instances—the show window, the residence and the street. There are many other places where a little thought will show that we are squandering a good deal of energy in order to produce an offensive glare while the incidental illumination could be much more agreeably produced by scattered lights of lower candle-power. In the case of the show window we can cover the lights so as to hide them from view altogether. There are some cases of store or room lighting where we could do the same to advantage; but for street lighting it is entirely out of the question. However, we can always use opal, ground glass or tinted shades over the lamps so as to dim the glare, and we can reduce the candle-power of our units so as to still further cut down the dazzling. Then when we increase the number of the lights and scatter them more widely we can get the one effect which we are seeking in each case: not an exhibition of intense and glaring lights whose dazzling power is enhanced by the deep shadows which they produce, but an illumination really worthy of the name.

THE RELATION BETWEEN THE ATOM AND THE CHARGE OF ELECTRICITY CARRIED BY IT.*

BY J. J. THOMSON, M.A., F.R.S.

(Concluded from page 325.)

Thus, on this view the chemical combination consists in the formation of an aggregate of a large number of H and Cl molecules, then the interchange of the charges on some of the atoms, then the formation of an aggregate of HCl molecules, and finally the breaking up of this aggregate into a number of separate molecules of HCl. It will be noticed that there are no atoms set "free" during the whole of the process. The presence of free-charged atoms during the progress of chemical combination between gases could be detected by experiments made on the electric conductivity of the mixture whilst the combination is proceeding. If free-charged atoms are present they will move under electromotive forces, and will cause the mixture of gases to act as a conductor of electricity. A method of testing the conductivity of gases and the results of experiments made with it are given in a Paper by the author (*Proc.* Camb. Phil. Soc., Vol. VIII., p. 258). These experiments showed that when a mixture of H and Cl was combining it did not possess any conductivity, thus proving that in these cases no charged atoms were set free during the combination. Some other cases of chemical combination gave the same result; on the other hand, there was a class of cases in which the mixture of gases acted as a conductor whilst chemical combination was going on. The experiments thus proved that in many cases of chemical combination no charged atoms are set free.

I also investigated this point by another method. Let us assume for a moment that free charged atoms are liberated during chemical action. To fix our ideas, let us take the case of a piece of zinc attacked by chlorine; suppose now that we electrify the zinc: if chemical action liberated free ions, or, supposing that an aggregation of atoms is necessary, if the algebraical sum of the charges on the atoms forming this aggregate were not zero, then when the electrified zinc atom enters into chemical combination an atom of chlorine must be set free carrying a charge of electricity of the same sign as that on the electrified zinc atom. Thus, in this case the charge would leak from the metal into the gas and the latter would cease to insulate. If, on the other hand, chemical combination went on between an aggregate of atoms, the algebraical sum of whose charges was zero, then, however much the zinc was attacked, there would be no liberation of charged atoms, and no transference of electricity from the metal to the gas.

I made an extensive series of experiments to find out whether an electrified metal plate when immersed in a gas by which it was chemically attacked did or did not lose its charge. I was never able to trace any leakage of electricity to this cause, even though two metal plates charged to a great difference of potential, either by a Wimshurst machine or by a battery of 2,000 small storage cells, were placed close together in the gas. The electrified surfaces were zinc, mercury and electrolytic solutions, the gases chlorine and nitrosyl chloride; but though the conditions of the surfaces showed that active chemical action had taken place, there was no escape of electricity through the gas, whether the surfaces were positively or negatively electrified. In these cases the chemical combination went on at the temperature of the room when there was no chance of the gas being dissociated. In the case of combination at very high temperatures when the gas may be dissociated we shall see later that there are cases where chemical combination does promote the discharge of electricity.

The aggregation of molecules, as described in the preceding sections, is one method by which the attractions between the oppositely electrified atoms in the molecule might be weakened sufficiently to allow chemical action to proceed. Another method by which the same end might be accomplished would be for the molecules to be immersed in, or to be close to the surface of, a conductor or substance of large specific inductive capacity. The effect of this, as explained in the *Philosophical Magazine*, Vol. XXXVI. p. 320, would be to diminish the attraction between atoms and allow them to be easily separated. The substance which acts as the bridge for the interchange of the charges on the atoms might be the substance which when collected into lumps served by its electrostatic action to diminish the attraction between the atoms. This method of producing chemical change closely resembles the preceding—in each of them the presence of a third substance is necessary, and in each of them the formation of molecular aggregates, but whereas on the first view the aggregates are those of the substances which are combining chemically, on the second they are formed by the third substance.

The hypotheses to which we are led by the preceding considerations may be summed up as follows:—

The forces between charged atoms placed very near together are modified by the electro-chemical properties of the atoms. In consequence of this, an electro-negative atom, if positively charged, cannot, in the absence of a strong external electric field, interchange its charge with the negative charge on an electro-positive atom, unless the two are connected by an external conducting circuit.

Chemical action does not, in general, take place between a single pair of molecules alone in the field, but requires the formation of aggregates either of the inter-acting molecules or of some third substance which is either a conductor of electricity or has a large specific inductive capacity.

In the preceding statement an element is called electro-positive or electro-negative, according as its Volta coefficient is negative or positive.

Thus, on these hypotheses, chemical combination between two elements involves in general two processes: (1) a process by which all the electro-positive atoms, half of which were originally positively and half negatively charged, all become positively charged, while the electro-negative atoms become all negatively charged; (2) the combination of these properly charged atoms to form a molecule of the compound.

In some cases the process of chemical combination seems only to reach the first stage, that of the interchange of charges between the atoms of the elements. If the process stops at this stage, the electro-positive substance will be charged with positive electricity, the electro-negative substance with negative electricity. If one of the substances, say the electro-positive, is a solid or a liquid, while the other is a gas, then at the surface of the solid or liquid there will be two layers, one of positive electricity on the solid or liquid,

* Abstract from the *Phil. Mag.*, Vol. XL., December 1895.

Digitized by Google

the other of negative in the gas. This double layer of electrification will make the electric potential discontinuous at the surface separating the two substances, the potential in the solid just inside the surface of separation exceeding that in the gas just outside the surface by a finite amount. The electrification produced by the splashing of drops is evidence of the existence of this double layer of electrification: when a drop of water or of mercury falls through air and splashes on a plate, the drop itself is positively electrified, while there is negative electrification in the surrounding air. On the view just given, this is an example of incomplete chemical combination: in the case of the water, the electrical interchanges preliminary to the formation of H_2O_2, the oxygen in the air getting the negative charge, have taken place; the second stage, however, does not go on, or at any rate is not completed during the falling of the drop. Thus the positively and negatively electrified atoms are not bound together so firmly as they are in a chemical compound, and get separated in the great extension of surface produced by the splashing. In the case of mercury the first stage of oxidation, that is the assumption of the negative charge by the oxygen and of the positive by the mercury, occurs, while the second either does not occur or is not completed during the fall of the drop. It would seem from the phenomena of drops that examples of this incomplete chemical action are very frequent, for the splashing of drops of the most widely different substances gives rise to electrification. In fact it seems possible that the existence of this double coat, and on our hypothesis of incomplete chemical action, is almost universal at ordinary temperatures, and that the electrification produced by the friction of heterogeneous substances is due to the partial rubbing off of this coating from one or both of the substances.

We shall now proceed to consider in the light of this hypothesis as to chemical action several simple chemical and electrical phenomena. We shall begin with the case of oxidation. Let us suppose that we have a zinc rod immersed in oxygen, and in order to take a case where the chances of combination are greatest, let us suppose that the oxygen molecules are dissociated by some external agent into atoms. Suppose that the combination begins, $\overset{+}{Z}n\overset{-}{O}$ being formed. Since a positive charge is withdrawn from the zinc and a negative one from the oxygen, the zinc and oxygen, which were originally electrically neutral, will now be charged negatively and positively, so that at the surface of contact of the zinc and the oxygen a charged condenser will be formed with its negative charge carried by the zinc atoms, its positive charge by the oxygen atoms. According to our hypothesis, zinc and oxygen atoms in these electric states do not combine unless connected by conducting circuits, so that, unless such circuits are present, for each molecule of ZnO formed there will be an increase in the charge on the condenser, and consequently an increase in its potential energy. The charge on the condenser is proportional to the number of molecules of ZnO formed, so that the electrostatic potential energy will be proportional to the square of the number of molecules; the diminution in the chemical potential energy due to the formation of ZnO is only proportional to the number of molecules of this substance. Thus the increase of the potential energy increases faster with the number of molecules of ZnO formed than the diminution in the energy; so that after a certain amount of chemical combination has occurred, any further combination will be attended by an increase in the total potential energy. When this point has been reached chemical combination will stop; so that under these circumstances only a limited amount of chemical combination will occur. Suppose now, however, that in addition to the zinc and oxygen other substances are present which can form conducting circuits between the negative zinc and the positive oxygen atoms, and thus enable these atoms to interchange their charges, so that the zinc becomes positively, the oxygen negatively electrified. In this state they can combine so that the condenser at the surface of the zinc will be discharged. As this condenser is constantly being discharged, there will be no increase in the potential energy due to it, and thus the progress of the chemical action will be accompanied by a diminution in the potential energy, and will therefore proceed until one or other of the substances is exhausted.

Similar considerations will show why but little chemical action goes on if zinc is immersed in acid, while the action proceeds freely when the zinc is connected to the acid by an external conducting circuit.

Observation seems to prove that a difference in the sign of the contact potential difference between two substances does take place when the circumstances are altered in such a way that we might expect great changes in the relative importance of these effects to occur. Thus there are cases where, when the substances are cold, when we should expect the chemical action to be sluggish, the electro-positive substance is at a higher potential than the electro-negative one, while when the temperature is that of red heat or higher, when chemical action is presumably more vigorous, the sign of the potential difference is reversed. Thus, for example, when a drop breaks off from a column of mercury and falls through oxygen, the mercury is positively, the oxygen negatively, electrified; again, when ultra-violet light falls upon a clean metal plate the metal is positively, the surrounding air negatively, electrified. In this case the sign of the potential difference indicates that the effect due to the interchange of charges overpowers that due to the chemical combination. If, however, we have a piece of metal above a red heat surrounded by air, the air will acquire a positive charge, the metal a negative one, so that in this case the effect of chemical combination overpowers any effect that may be due to the interchange of atoms.

The contact of the zinc with the solution in the preceding example thus gives rise to the formation of two layers of atoms, one layer being positively, the other layer negatively electrified. When the solution is very weak, this double layer which is interposed between the zinc and the solution consists of a layer of partly dissociated zinc molecules, the positive atoms being next the solution, the negative atoms next the zinc plate. If the solution is strong, the transition between the zinc and the solution is made by a layer of partly dissociated molecules of the salt, the positive layer, consisting of zinc atoms, being next the zinc, the negative layer, consisting of atoms of the electro-negative constituent of the salt, being next the solution. In the case of the contact of a metal and the electrolyte, the work required to produce the double electrical layer which gives rise to the potential difference is in the preceding investigation supposed to be done by the osmotic pressure. There is, however, another source of energy quite adequate to produce potential differences at the surfaces of contact of different substances, and which is available in the case of solids as well as liquids. This source is surface-tension. Every unit of area of the surface of separation of two substances, A and B, contributes an amount of potential energy equal to the surface-tension between A and B. Now Lord Rayleigh has shown (*Phil. Mag.*, October, 1883, p. 315) that, if the transition from A to B, instead of being abrupt, takes place through a thin layer (whose thickness need only be commensurable with molecular distance) whose properties are intermediate between A and B, the potential energy due to surface-tension will be diminished. This diminution in the potential energy will produce a tendency for such a transitional layer to be formed, even though the formation of the layer is accompanied by a double layer of electrification. The energy rendered available by a sensible diminution in the surface tension will be more than sufficient to charge the double layer of electrification up to a potential difference amounting to a large fraction of a volt. For if the distance between the electrified layers is 10^{-8}cm., and their potential difference 1 volt, the energy per unit area of the condenser formed by the double layer will be equal to $10^{16}/8\pi \times 10^{-8} \times 9 \times 10^{20}$, or about 44 ergs. If the surface tension were the same as that of water, the energy due to it would be 78 ergs per square centimetre, so that if any sensible diminution in this took place the energy rendered available would suffice to charge up the layer to a potential difference comparable with a volt. Even if the formation of this layer required as a preliminary chemical decomposition to liberate the charged atoms forming the layer, and this decomposition required a supply of energy, there would still be plenty available for this purpose. The thickness of the layer is comparable with the range of molecular forces; thus the quantity of matter in it, and therefore the amount of chemical decomposition, will be exceedingly small, so small as to be quite imperceptible by chemical means, but small as it is it may, in consequence of the enormous electric charges carried by the atoms, be sufficient to produce a finite potential difference between the coats of the double layer.

The amount of energy which would be liberated by a diminution in the abruptness of transition, and the effects which this might be expected to produce, are, I think, much greater than is generally suspected. Thus we should, for instance, expect that the abruptness of transition between, say, a metal like mercury and a gas like oxygen, would be diminished if between the mercury and the gas there was a film of the compound of the two: the tendency to form this compound would be very great, for if the film of oxide only diminished the surface tension by one per cent., enough energy would be liberated to suffice to raise the temperature of a film of oxygen 10^{-5}cm. thick several hundred degrees Centigrade. With this amount of energy available, it is difficult to avoid the conclusion that even the least oxidisable metals must, when exposed to air, be coated with a thin film of oxide, and though this film is too thin to be detected, either by chemical or optical means, it may yet, as we have seen, produce appreciable electrical effects. The same effects, too, might be expected to take place between solids: thus, if copper and zinc were brought into intimate contact, there would be a tendency for a layer of brass to form between them. It does not seem impossible that, under favourable circumstances, the zinc and copper might be cemented together by this film of brass.

This consideration, too, must have an important application to the electrification due to the splashing of drops; this phenomenon requires the existence of a double coating of electricity over the

Digitized by Google

surface of the drop; to provide the atoms which carry the charges on these coatings chemical decomposition may have to take place. The energy for this may come from the lowering of the surface tension produced by the formation of an intermediate layer, so that at the surface of the drop chemical changes may take place, of which we have, at ordinary temperatures, no experience from experiments made with large masses of the substances.

Contact Difference of Potential between a Metal and a Coating of Oxide.

If we have a metal plate covered with a film of oxide or other compound of the metal, the transition from the metal to the air will be more gradual if the molecules of the compound in the part of the film near the plate are arranged so that the metal atoms are next the plate, and the oxygen atoms on the far side. In the molecules of the oxide, the metal atoms carry the charge of positive electricity, while the oxygen atoms carry the negative charge: there will thus at the surface of the plate be a double coating of electricity, the positive side of this layer being next the plate; the potential, therefore, will fall as we pass from the metal to the layer of oxide—that is, the oxide will be negative to the metal. This agrees with the results obtained by those who have experimented on contact electricity, and it further appears, as a possible interpretation of their experiments, that the potential difference between a metal and its oxide may amount to a considerable fraction of a volt.

Communication of Electricity from the Electrified Atoms of a Gas to a Conductor.

This is only another aspect of the preceding question. For suppose we have a number of electrified atoms of a gas in contact with a metal, and that the metal is electro-positive to the gas, the electricity can go from the gas to the metal in the following ways: (1) If the atoms of the gas are negatively electrified, they may combine with positive atoms of the metal to form a neutral compound, leaving an excess of the atoms of the metal negatively electrified. Or, if the atoms of the gas are positively electrified, then, if any substance is present which can form conducting chains between the atoms of the gas and those of the metal, the atoms will interchange their charges, the positive charge going to the electro-positive substance and the negative to the electro-negative. Those atoms of the gas which were positively charged might unite with those negatively charged to form molecules, so that the gas itself would emerge electrically neutral after contact with the metal.

It will be seen that each of these methods requires something more than mere contact of the gas and metal; this seems borne out by the phenomena exhibited by electrified gases. It was shown by Giese that electrified gases from a flame could pass through wire gauze connected with the earth, and yet retain their charges: this fact is exemplified in a very striking way by Lord Kelvin's electric strainers, as he finds that electrified gases still retain an appreciable fraction of their charges after passing through these strainers, which consist of many layers of wire gauze placed one behind the other. In an experiment I described in the B.A. Report for 1894 ("The Connection between Chemical Combination and the Discharge of Electricity through Gases"), an electrified gas retained its charge though enclosed in a vessel with a large pool of mercury connected to the earth. I have also found that such gases retain a large proportion of their charge after bubbling through a mixture of sulphuric acid and water. In a Paper "On the Passage of Electricity through Hot Gases" (*Phil., Mag.*, [5] XXIX., p. 444), I showed that when a current is flowing through a hot gas a piece of cold metal interposed between the electrodes completely stops the current, though when the metal gets red hot the current passes through it with ease. In all these cases the charged atoms would be striking against conductors, so that they furnish very strong evidence that this process alone is not sufficient to rob the atoms of their charges.

The first of the processes alluded to above would tend to make a gas lose a negative charge or the metal a positive one, while the second process would make the gas lose a positive charge, the metal a negative one. This is on the assumption that the metal is electro-positive to the gas; if it were electro-negative, the words positive and negative must be interchanged in the preceding statement.

The first process involves chemical combination, thus anything tending to promote combination, such as a high temperature of the gas or metal, would increase this effect; we should therefore expect to find evidence of this effect in the case of hot bodies. A very good instance of this effect is the fact, discovered by Guthrie, that a hot ball of iron could retain a negative charge when it could not retain a positive one. The experiments of Elster and Geitel also illustrate this point. Again I found (see *Proc.* Roy. Inst., April 13, 1894), that if in a vessel containing hydrogen (and probably a little air) at a low pressure, we split up some of the molecules of the gas so as to get a supply of positively and negatively electrified atoms, a red-hot clean copper rod connected with the earth would discharge the negative electricity and leave the positive behind. The negative electricity escapes from the gas, since the negatively electrified gaseous atoms combine chemically with the positive atoms of the metal. If, however, a red-hot copper rod thickly coated with oxide is placed in the gas, the *positive* electricity escapes from the gas through the rod to the earth. This is in accordance with the theory; the chemical process which now goes on is the reduction of the oxide: and this is effected by the positive hydrogen atoms combining with the negative oxygen atoms; thus the process affords a means of escape to the positive electricity in the gas, but not to the negative.

The second process by which we have explained the escape of electricity from a gas is that of the interchange of charges between oppositely-charged atoms. As the tendency for this process to take place arises from the Volta effect, it will be great when we have a number of strongly electro-positive atoms charged with negative electricity near a number of electro-negative ones charged with positive electricity. Thus we should expect the effect to be great when one of the substances is an electro-positive metal, as when this is in an electrically neutral state half the strongly electro-positive atoms are charged with negative electricity, and on account of the Volta effect there is a great tendency for them to lose their charges. When, however, we have an electrolyte instead of the metal we should expect the effect to be much smaller, as in an electrolyte the electro-positive element has the positive charge, the electro-negative one the negative; it might, however, still exist to some extent if, for example, the electrified gas in contact with the electrolyte were more electro-negative than the negative element of the electrolyte, and if the gas carried a positive charge.

This difference between metals and electrolytes may perhaps be the explanation of the fact that, whereas a sheet of metal when illuminated by ultra-violet light rapidly loses a negative charge while it can retain a positive one, this effect being most pronounced the more electro-positive the metal, an electrolyte, on the other hand, when exposed to ultra-violet light does not lose its charge, whether this be positive or negative.

Another example of the discharge of electricity by the second process is that in the glow discharge from a metal where the temperature is low the negative discharge occurs more easily than the positive—*i.e.*, the potential difference between the point from which the electricity escapes and the nearest large conductor is less when the point is negatively electrified than when it is positively. It would be interesting to see whether this difference would still persist if the point from which the discharge takes place were made of an electrolyte and not of metal. On the hypothesis we have just been describing we should expect the difference to be much reduced by the substitution of an electrolyte for the metal. Some recent experiments by Prof. S. P. Thompson show that the conditions of discharge are modified when lead peroxide is substituted for metal.

When a glow discharge takes place from a metal point connected directly with a Ruhmkorff coil or a Wimshurst electrical machine the surrounding gas gets negatively electrified. This, however, is not always the case if we connect the point from which the discharge takes place to an instrument producing potential differences greatly exceeding those given by a Ruhmkorff coil. A very convenient form of such an instrument is the one described by Prof. Elihu Thomson, which is a transformer whose primary is a coil connecting the outside coatings of two Leyden jars, while the secondary is a coil with a large number of turns carefully insulated from the primary. When the oscillating current produced by discharging the jars passes through the primary, the electromotive force induced in the secondary is able to induce sparks of great length. Using a transformer of this kind instead of the Ruhmkorff coil, Harvey and Hird (*Phil. Mag.*, Vol. XXXVI., p. 45) and Himstedt (*Wied. Ann.*, LII., p. 473) found that when the point discharged in oxygen, the gas was *positively* electrified, while when it discharged in hydrogen, the hydrogen was negatively electrified, just as when the Ruhmkorff is used. The very intense field produced by the transformer would split up the molecules of the gas and promote direct combination between the metal and the gas; this, as we have seen, would cause the gas to be positively, the metal negatively, electrified, and this, as we have seen, is what happens in the case of oxygen, though not in that of hydrogen. In the case of the electrification of the air in a vessel into which a point is discharging, we have to consider not only the communication of electricity from the point to the gas, but also the diffusion of the electrified atoms of the gas from the neighbourhood of the point through the vessel. Any difference in the rate of diffusion would, even though the communications of + and − electricity from the point to the jar were made with equal ease, give rise to an electrification of the gas. Imagine, for example, that negatively electrified atoms diffuse through the gas more quickly than positively electrified ones; then, if the rates of emission of + and − electricity were the same, the negatively electrified atoms would get further from the point than the positive, so that the outlying regions would get a charge of negative electricity; the region round the point would be charged with positive

Digitized by Google

electricity, part of this would leak back into the point, leaving the gas as a whole negatively charged. Several phenomena, which I shall now proceed to describe, have led me to the conclusion that the effects due to the communication of the electricity from the metal to the gas are masked in many cases by the difference in the rates at which the electrified atoms diffuse, the negative atoms in all my experiments diffusing more rapidly than the positive ones. In the case of oxygen, where the gas gets a positive charge, the strong tendency for the oxygen to combine with the metal is sufficient to overcome the more rapid diffusion, whereas with such gases as hydrogen and carbonic acid, where the tendency to combine is weaker, diffusion gets the upper hand.

I made several experiments with chlorine, using different materials for the discharging point. The first substance I tried was silver chloride which had been fused into a solid mass; when this point was connected to one of the terminals of the high-tension transformer, the chlorine was negatively electrified. I then used a zinc point, protecting the zinc before the experiment began by covering it with a glass tube, through which it was pushed just before the discharge began; in this case, again, the chlorine was negatively electrified to a slight extent. I then replaced the zinc point by a sodium one, protecting this in the same way as the zinc by a glass tube; when the discharge passed from the sodium point, the chlorine was *positively* electrified. Thus by using a substance such as sodium, which has a very great affinity for chlorine, we are able to overcome the effect of diffusion, and get a positive charge in the gas, just as when the discharge passes from a copper point into oxygen.

The following experiments seem to show that a negatively electrified hydrogen or oxygen atom moves more quickly under equal electric intensities than a positively electrified one.

The outside coatings of two Leyden jars, A, B (Fig. 6), were connected by a wire wound into a coil C. In this coil an exhausted bulb was placed and a platinum wire fused into the bulb; this wire was connected with an electrometer. The inside coatings of the jar were connected with the terminals of an induction coil through the primary of which the alternating current used for lighting the

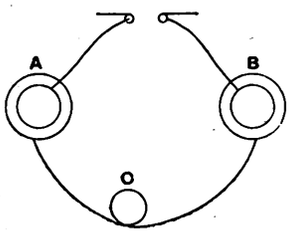

FIG. 6.

laboratory passed. This caused an arc discharge to pass between the terminals of the induction coil, and produced a potential difference between the insides of the jars. This potential difference can be very greatly increased by directing a blast of air on the space between the terminals of the induction coil, and so blowing out the arc. If we now examine the electrical state of the platinum wire in the bulb, we shall find that when the blast is on the wire acquires a positive charge when placed near the equator of the bulb (by the equator of the bulb we mean the region inside the bulb adjacent to the coil which encircles it), and a negative charge when placed near the pole. If, however, after the blast has been on for some time, it is suddenly stopped and the arc allowed to pass between the terminals of the induction coil, the sign of the electrification is reversed, the platinum wire now acquiring a positive charge when placed at the pole of the bulb and a negative charge when placed at the equator. Both these results are, I think, explicable if we suppose that the negative atoms diffuse more rapidly than the positive ones. For, take the case when the arc is blown out. Here there is a great potential difference between the electrodes, and the coil surrounding the bulb is raised to a high potential. This causes a brush discharge to start from the glass into the rarefied gas in the bulb, the discharge starting from the part of the glass nearest the coil, *i.e.*, from the equator. If, now, the negative atoms travel faster through the bulb than the positive, then, even though the same number of the two kinds of atoms start from the glass, the negative atoms will be in excess in the region remote from the origin of the discharge, while near this origin the positive atoms will be in excess: thus we shall have positive electrification at the equator, negative electrification at the poles. Let this go on until a number of positive and negative atoms are dispersed through the bulb. Then stop the blast. This at once greatly diminishes the potential difference between the terminals of the induction coil, and lowers the potential of the coil surrounding the bulb to such an extent that the brush discharge no longer takes place from the glass: the electric intensity in the bulb is lowered, so that no further decomposition of the gas takes place, and the bulb now does not show any luminosity. The charged atoms produced by the previous discharge linger for some time in the bulb before recombining, and move under the electric intensity due to the oscillating currents in the coil; the lines of electric intensity arising from the induction due to these currents are circles, with the line joining the poles of the bulb for their axis. Under these forces the atoms will tend to describe these circles; and since the negative ones move more quickly than the positive ones, the negative atoms will be revolving round the axis of the bulb with greater rapidity than the positive ones; hence, on account of centrifugal force, there will be an excess of negative atoms at the equator, and consequently an excess of positive ones at the pole: thus the equator will be negatively, the poles positively electrified. This electrification is, however, only transient, as the opposite charged atoms soon recombine.

If the negative atoms move more quickly than the positive ones, then in a discharge tube in a steady state the pressure at the positive electrode must be higher than that at the negative. For at any part of such a tube where there is no excess of positive electrification, the number of negative atoms which in unit time cross a section of the tube is greater than the number of positive ones. There will thus be a stream of *atoms* towards the positive electrode: to keep the pressure in the tube constant, we must compensate this by a stream of *molecules* from the positive to the negative electrode.

The potential gradient will vary inversely as the pressure of the gas, and the ratio of the pressure at the positive electrode to that at the negative will depend upon the square of the reciprocal of the pressure.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

SATURDAY, January 11th.

ASSOCIATION FOR THE IMPROVEMENT OF GEOMETRICAL TEACHING

11 a.m and 2 p.m. Meeting at University College, Gower-street.

TUESDAY, January 14th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read: "The Sanitary Works of Buenos Ayres: Sewage, Drainage and Water Supply," by the Hon. R. C. Parsons.

WEDNESDAY, January 15th.

ROYAL METEOROLOGICAL SOCIETY.

7:45 p.m. Annual General Meeting at the Institution of Civil Engineers, 25, Great George-street, S.W.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Annual Meeting at 20, Hanover-square. Presidential Address by A. D. Michael.

THURSDAY, January 16th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Presentation of Premiums, Inaugural Address of the President, Dr. John Hopkinson. M.A., F.R.S.

FRIDAY, January 17th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "Iron Tunnels," by W. O. Leitch, Jun.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "More about Argon," by the Right Hon. Lord Rayleigh, F.R.S.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Acute Hearing of Telephone Operators.—*Electric Power* states that a very high degree of sharpness of hearing is developed by telephone exchange girls. In the case of exchanges fitted on the Law system, on which it is customary to call up the number of the subscriber and then to state one's own number, the girls often do not wait to hear the second number mentioned before making the required interconnection. It is said that their delicate ears detect individual characteristics in the *timbre* of each transmitter, or idiosyncracies in the clatter made in unhooking the receiver and switching on; and it is these characteristic sounds which, so the story goes, enable the girls to locate the subscriber calling up.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

OVERPRODUCTION.

An exceedingly sanguine man is Mr. HENRY FLOY, of America. Having discovered by a partial application of the statistical method that, contemporaneously with an unlimited faith in the future of electricity, there exists in the United States, as elsewhere, a decidedly limited demand for electrical engineers, and that, as a consequence, "the opinions and lives of many individuals are erroneously shaped," Mr. FLOY concludes it is "time for those who realise the situation to set about correcting the existing misconceptions." As if anything short of actual contact with hard facts had ever dissipated a pleasant popular fallacy. However, whether it is agreed or no that Mr. FLOY's attempt to stem the flowing tide with a magazine article is an attempt to perform the impossible, the results of his inquiries are of some interest. Struck by the alarmingly small ratio which the apparent supply of suitable positions bears to the undoubted demand for them by the twelve hundred ambitious young men annually graduating as electrical engineers, Mr. FLOY, like a true American, proceeded to send out some 260 personal letters to the present-year graduates in electrical, mechanical and civil engineering from Cornell and Lehigh Universities and the Massachusetts Institute of Technology, and—strange to relate—received no less than 122 "most interesting, courteous and complete" replies. We shudder at the thought of the replies, which would probably have been received in this country had anyone ventured to interrogate English engineering graduates in an equally inquisitorial fashion. The replies would assuredly have proved interesting, but possibly neither courteous nor complete. One probable point of similarity is, however, mentioned by Mr. FLOY: "the letters written by the graduates of one college were particularly noticeable as indicating their authors' lack of training in the use of good English."

Turning now to the statistical data gleaned by Mr. FLOY, and presented this month to the readers of the *Engineering Magazine*, in an article entitled "Are we Educating too many

Digitized by Google

Electricians?" let us see what they reveal, bearing in mind the author's modest estimate of them as "strong indications of probabilities," not proofs. To would-be electrical engineers he sent out 108 circulars, and received 52 replies. These *tend* to show that while a greater percentage (78·8 per cent.) of electrical engineering graduates secured employment, as compared with civil and mechanical engineering graduates, they only did so in virtue of the fact that they had taken up positions in which their electrical training was so much pure waste, and because they were content to accept considerably lower pay. It is also worthy of notice that almost twice as many electrical men secured employment through the influence of relatives than was the case with the mechanical or civil men. This is really too disheartening. We have frequently been asked for advice by potential engineers as to the best branch to specialise in, and our invariable counsel has been: Exercise great care in choosing your father, and then join *his* branch. We have always flattered ourselves, however, that this well-known dictum did not apply to electrical engineering. But if Mr. FLOY's statistics indicate "strong probabilities," nepotism is more flourishing in the profession of electrical engineering —at any rate in America—than it is in the more ancient engineering professions.

Is there not good reason to believe that we in England are also educating too many electrical engineers? The same idea prevails, it is true, about every profession in this overcrowded little island; but whilst it is sombrely acquiesced in by harassed fathers as regards, say, the legal or the medical profession, it is in the case of electrical engineering only prevalent amongst the initiated. Hence the stream of youth impinges upon electrical engineering with tremendous force, which nothing but the irresistible logic of facts will diminish. Meanwhile, it may be asked whether there would not at least be greater contentment among young electrical engineers if they were less elaborately prepared for posts they are destined never to occupy. Assuming, for the sake of argument, that the average college electrical engineering course is all that could be wished as a mental equipment, does it not tend to foster an intense dislike, if not a positive disability, for the dull routine work which forms so large a part of the general engineering work of the world? No doubt the training now fashionable is an excellent machine for turning out demonstrators, professors, and engineering investigators, but is it to be compared with that received through the medium of the shops, drawing office, works test-room, evening class and miscellaneous outside experience so far as the filling of the more numerous and less exalted posts with contented, competent men is concerned? The man whose mind is enriched with sound scientific knowledge has intellectual resources and interests unknown to his less elaborately trained competitor; but is he as a rule likely to regard his college education merely as a means of enlivening the drudgery of his mechanical day-stint? Will he not rather come to look upon his two or three years' college course as a long lane leading nowhere, unless it leads to congenial employment, and a remuneration more commensurate with his many accomplishments? In short, will the "techniker" be as contented with his lot as the man who lacks "the burden of lean and wasteful learning." The *tendency* of the supply is, of course, to accommodate itself to the demand; but the process is sometimes long, and, in matters of this kind, always painful. It may be perfectly true, economically speaking, that there is no such thing as over production, but merely "ill-assorted" production; but when the ill-assorted product is a human being the distinction becomes indistinguishable.

ELECTROMAGNETIC THEORY.—LXXXI.*

BY OLIVER HEAVISIDE.

(*Continued from page 278.*)

§ 322. The following way of regarding the matter is useful in combinations. It has the advantage of compactness. Imagine any combination to be disturbed by the impression of a current upon it. Let the current be h, and its point of entry be denoted by y. Then

$$h = Y_y V_y, \quad \text{or} \quad V_y = \frac{h}{Y_y}, \tag{76}$$

is the connection between h and V_y, the resulting potential at y, if Y_y is the conductance operator there, or the sum of the conductance operators of the paths open to the impressed current. The path of entry is not counted.

If Y_y is known, (76) may be algebrised as it stands. But to represent an initial state of charge or electrification, let $h = pQ$, where Q is constant. Then

$$V_y = \frac{pQ}{Y_y} \tag{77}$$

expresses the potential at y due to the impulsive entry of the charge Q; and its expansion is

$$V_y = \Sigma \frac{Q\epsilon^p}{Y_y'} + \text{steady term}, \tag{78}$$

ranging over the roots of $Y = 0$, the accent meaning differentiation to p. There is a steady term if p/Y_y is finite when $p = 0$. This is exceptional.

Now to find V_x, the potential at some other point x in the combination, we require to multiply V_y by the operator V_x/V_y; as in

$$V_x = \frac{pQ}{(V_y/V_x)Y_y}. \tag{79}$$

But in a normal state, such as the general term of the expansion refers to, we must multiply by u_x/u_y, if u is the normal function. This makes

$$V_x = \Sigma \frac{Qu_y u_x}{u_y^2 Y_y'} \epsilon^{pt} = \Sigma A u_x \epsilon^{pt}. \tag{80}$$

Now, the coefficients A are subject to the conjugate property, and determined by (62). The numerator Qu_y agrees. So the denominator is U − T. Or

$$V_x = \Sigma \frac{Qu_y u_x}{U - T} \epsilon^{pt}. \tag{81}$$

But U − T represents an integration extended over the whole system. It is fixed when u is fixed at any point, and has nothing to do with the value of y, the position of Q. Therefore the alternative form of U − T shown in (80) must be independent of the position of y, so that

$$V_x = \Sigma \frac{Qu_y u_x}{u_z^2 Y_z'} \epsilon^{pt}, \tag{82}$$

where z is any point, and Y_z the conductance operator there. (But do not choose a place where u vanishes, as that will require a compensating infinity.) Lastly, if there are only two paths meeting at z, we have the equivalent form

$$V_x = \Sigma \frac{Qu_y u_x}{-c_z^2 Z_z'} \epsilon^{pt}, \tag{83}$$

by (66), (68), where c_z is the normal current at z, corresponding to u_z, and Z_z the resistance operator there. This form is perhaps more generally useful.

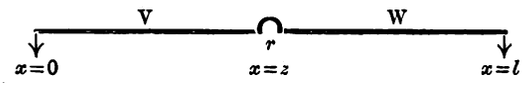
An integration over the whole combination will determine the value of A so far as it depends upon initial charge. If further, there is initial magnetic energy, it must be allowed for as in (62). It is important to think of the normal function u as a single function. It may, indeed, have various forms of algebraical expression in different parts of the combination, but that is of no consequence in the present connection.

§ 323. Example should supplement precept, if it does not precede it, which may be better still. Therefore, let us apply

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

the above to the case of two cables of different types joined in sequence, with an intermediate insertion. Let r be the



resistance operator of the insertion (containing no leak), which is made at the distance z from $x=0$. The resistance operator of the combination, reckoned at z, is

$$Z = r + \frac{R_1}{s_1}\tan s_1 z + \frac{R_2}{s_2}\tan s_2(l-z), \qquad (84)$$

the cables having different R and S. Here Z is such that e/Z is the current at z due to e there.

Now put Q at y, less than z. If the normal potential function u of the last section is v in the first cable and w in the second, and the resulting potentials are V and W, we have

$$V = \Sigma \frac{Qv_y}{U-T} v\epsilon^{pt}, \qquad W = \Sigma \frac{Qv_y}{U-T} w\epsilon^{pt} \qquad (85)$$

But if Q is in the second cable, then

$$V = \Sigma \frac{Qw_y}{U-T} v\epsilon^{pt}, \qquad W = \Sigma \frac{Qw_y}{U-T} w\epsilon^{pt}. \qquad (86)$$

In these, v, w, V and W refer to the variable point x, whilst Q refers to y.

We have next to specify the nature of v, w. Since the first cable is earthed at $x=0$, and the second at $x=l$, we may put

$$v = \sin s_1 x, \qquad w = a\sin s_2(l-x), \qquad (87)$$

provided a is settled so as to harmonise them. This is to be done by the continuity of the current at z; that is,

$$\frac{s_1}{R_1}\frac{dv}{dx} = \frac{s_2}{R_2}\frac{dw}{dx}, \quad \text{at} \quad x=z. \qquad (88)$$

This makes

$$w = -\frac{R_2 s_1}{R_1 s_2}\frac{\cos s_1 z}{\cos s_2(l-z)}\sin s_2(l-x). \qquad (89)$$

The normal function being complete, it remains to evaluate U – T for it. Since we know Z at the point z, the shortest way is by $-c^2Z'$. Thus

$$V = \Sigma \frac{Q\sin s_1 x \sin s_1 y}{-\left(\frac{s_1}{R_1}\cos s_1 z\right)^2 \frac{dZ}{dp}} \epsilon^{pt} \qquad (90)$$

is the potential at x due to Q at y, when both x and y are in the first cable, Z being given by (84). The summation ranges over the roots of $Z=0$. There is no steady term, because of the earth connection. For d/dp may be substituted differentiation to s_1 or s_2 for trigonometrical convenience, and so we come to the fully-developed formula, suitable for calculation if required. In general r is a function of p. But we do not need to allow for that unless there is initial energy in r itself.

If x is in the second cable, y being still in the first, we must put w for v in (90). If x and y are in the second cable, use w_x and w_y in the numerator. If y is in the second cable and x in the first, use w_y and v_x. In short, follow (85), (86).

If the effect of a localised impressed voltage is wanted, we may use the resistance operator at the place. Thus, when e is at Z, then

$$C = \frac{e}{Z} = \frac{e}{Z_0} + \Sigma \frac{e}{pZ'}\epsilon^{pt}, \qquad (91)$$

where z is as in (84), and Z_0 is the steady resistance. To find C at any other place x, introduce the factor c_x/c_z in the general term. It is the ratio of the normal current functions at x and z, and is known.

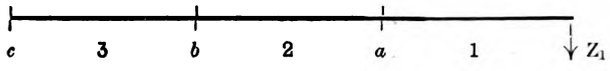
If e is at $x=0$, a different Z is needed. We may regard it as the resistance operator of the first cable with a terminal arrangement, say Z_1, given by

$$Z_1 = r + \frac{R_2}{s_2}\tan s_2(l-z). \qquad (92)$$

It is then a special case of (59), § 291. Again, if e is at $x=l$, we may bring the case under the same formula by treating it as a cable (the second one) with a terminal arrangement

$$Z_2 = \frac{R_1}{s_1}\tan s_1 z. \qquad (93)$$

It may also be noted that the same formula allows us to construct the resistance operator of any number of cables of the same or different types put in sequence, with intermediate insertions. For instance, we know the resistance operator at



a of cable 1 with Z_1 at its end. Call it Z_2. It is

$$Z_2 = \frac{R}{s}\frac{(R\sin + Z_1 s\cos)sl}{(R\cos - Z_1 s\sin)sl}, \qquad (93A)$$

using the proper R and s for the first cable. Then, by the same formula, we know the resistance operator at b of cable 2 with Z_2 at its end. Call it Z_3. Then we know the resistance operator at c of cable 3 with Z_3 at its end. That is, we know the resistance operator at c of the complete combination. This process may be continued to any extent, and results in a continued fraction, which soon assumes gigantic size. There may be intermediate insertions (without leaks), without essential change. But leaks require a little change of treatment. Say there is a leak at a, then Z_2 is to be the resultant resistance operator of the leak and that of the cable 1 with Z_1 at its end; that is, the reciprocal of the sum of their reciprocals. Using this modified Z_2, we may proceed as before till we come to the next leak, say at b, where we make a similar modification.

If an intermediate resistance operator is wanted, that is merely the sum of the resistance operators to right and left, to be got by the same process, which applies when the cables are not each of uniform resistance and permittance, and when the inductance and leakance are not ignored. Of course, however, when R and S vary in any one cable, its resistance operator requires special investigation.

§ 324. Still keeping to two cables in sequence, for simplicity of illustration of broad principles, let one be an ordinary cable, the other with R and S varying in such a way as to produce another kind of normal function. In passing, it may be observed that by causing R and S to change gradually from uniformity of distribution to various other arrangements of the same total resistance and permittance, we can continuously deform the simple normal function $(\sin sx + a\cos sx)$ so as to make it assume the shape of any other kind of normal function. In case of two kinds of cables, the results will be exhibited in two series, say a Fourier series for one cable, and a Bessel series for the other, properly harmonised.

In order to have the zeroth Bessel normal function, we need only let the conductance and permittance per unit length of cable both vary directly as the distance from $x=0$. There are other ways, but this is the simplest. Thus, the circuital equations

$$-\frac{dV}{dx} = RC, \qquad -\frac{dC}{dx} = Sp V, \qquad (94)$$

unite to make the characteristic

$$\frac{d}{dx}\left(\frac{1}{R}\frac{dV}{dx}\right) = SpV, \qquad (95)$$

without assumption of constancy of R and S. Therefore, if

$$\frac{1}{R} = \frac{x}{R_0}, \qquad S = S_0 x, \qquad (96)$$

R_0, S_0 being constant, we produce the characteristic

$$\frac{1}{x}\frac{d}{dx}x\frac{dV}{dx} = RSpV = q_0^2 V, \qquad (97)$$

where RS is the constant R_0S_0.

The proper solution for our purpose is

$$V = I_0(q_0 x)\,.\,A = \left(1 + \frac{(q_0x)^2}{2^2} + \frac{(q_0x)^4}{2^2 4^2} + \ldots\right)V_0, \qquad (98)$$

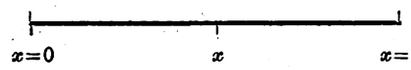
where V_0 is a time function, and I_0 is defined by the expansion given. The corresponding C is

$$C = -\frac{1}{R}\frac{dV}{dx} = -\frac{q_0}{R}I_1(q_0x)\,.\,V_0, \qquad (99)$$

where I_1 is the derivative of I_0.

Digitized by Google

The meaning of V_0 is clearly the potential at $x=0$ itself, given as a function of the time. But we do not want that particularly. In fact, since the



conductance is zero at $x=0$, there is no current there due to any finite impressed voltage, and we should avoid the point $x=0$ for our immediate purpose. We have

$$\frac{V}{C} = -\frac{R}{q_0}\frac{I_0(q_0x)}{I_1(q_0x)} \qquad (100)$$

at x. Therefore, if e is impressed at λ, the resistance operator is

$$Z = \frac{R_0}{q_0\lambda}\frac{I_0(q_0\lambda)}{I_1(q_0\lambda)}, \qquad (101)$$

if we now reckon the current positive from λ to 0. That is, e/Z is the current entering at λ, if there is earth on the other side of e. Or, more generally, V/Z is the current at λ when the potential there is V variable anyhow, due to sources on the side of λ beyond the cable in question.

The formula for the potential at x is simply got by (98), observing that it must reduce to e at $x=\lambda$. Thus,

$$V = \frac{I_0(q_0x)}{I_0(q_0\lambda)}e, \qquad (102)$$

from which C follows by a differentiation according to Ohm's law.

By (102), we see that

$$I_0(q_0\lambda)=0, \quad \text{or} \quad J_0(s_0\lambda)=0, \qquad (103)$$

is the determinantal equation, if $q_0^2=-s_0^2$. Here J_0 is an oscillating function analogous to the cosine. Why we should have it so will be seen on remembering that there is no current at $x=0$, so that, if R and S were constant, the normal function would be $\cos sx$.

Applying the expansion theorem to (102), where e is steady, V expands to

$$V = e + e\Sigma\frac{I_0(q_0x)\,.\,\epsilon^{pt}}{p\frac{d}{dp}I_0(q_0\lambda)} = e + e\Sigma\frac{J_0(s_0x)\,.\,\epsilon^{pt}}{\frac{1}{2}s_0\frac{d}{ds_0}J_0(s_0\lambda)},$$

or

$$V = e - e\Sigma\frac{J_0(sx)\,.\,\epsilon^{pt}}{\frac{1}{2}s_0\lambda J_1(s_0\lambda)}, \qquad (104)$$

if J_1 is the negative of the derivative of J_0. This shows the manner of establishment of the final state of V, which is $V=e$ all over, owing to the vanishing conductance at the far end.

We can, of course, put on any terminal Z_0 in place of earth on the other side of e, and solve in a similar way, but that would be premature at present.

§ 325. Pass to the matter immediately in question—namely, the harmonisation of the solutions for two cables of different natures. Let the cable on the left be of the regular kind, and

that on the right be of the kind considered in the last section. Earth is on at $x=0$ in the first cable, but the $z=0$ end of the second cable is virtually insulated, if that is the point of vanishing conductance. We measure x from left to right in the left cable, in which the potential is V, and z from right to left in the other, where the potential is W. Between them, at $x=l$ in one and $z=\lambda$ in the other cable, is inserted any combination r without leakage. The complete resistance operator at r is

$$Z = r + \frac{R}{s}\tan sl + \frac{R_0\lambda}{q_0}\frac{I_0(q_0\lambda)}{I_1(q_0\lambda)}, \qquad (105)$$

by (101), using the notation of the last section for the Bessel cable, except that x is now z, to distinguish it from x in the first cable. So the impressed voltage e at r produces the current

$$C_\lambda = \frac{e}{Z} = \Sigma\frac{e\,\epsilon^{pt}}{pZ'}, \qquad (106)$$

subject to $Z=0$, with the form of Z shown by (105).

This being merely a special case, let us examine the result of charging both cables initially in any given way, and leaving them to themselves. The formulæ are (85) and (86), provided we harmonise v and w, and evaluate U – T. The form of v is obvious, so

$$v = \sin sx, \qquad w = bI_0(qz), \qquad (107)$$

where b has to be found so as to make w fit v properly. This may be done by the voltage equation at the junction, or

$$v - w = rc, \qquad (108)$$

where $x=l$ in v and $z=\lambda$ in w, and c is the current corresponding to v. It is also the current corresponding to w, and their equalisation produces the determinantal equation (105) already found. Now (108) is the same as

$$\sin sl - bI_0(q_0\lambda) = -\frac{rs}{R}\cos sl, \qquad (109)$$

which gives b, and makes

$$w = \frac{I_0(q_0z)}{I_0(q_0l)}\left(\sin sl + \frac{rs}{R}\cos sl\right). \qquad (110)$$

This w is the other part of the normal system u, for v and w together make it complete, except as regards the internal variation in r itself, which we do not want.

There is only left the evaluation of U – T. As before, the resistance operator at r being known, we may employ the $-c^2Z'$ form, and therefore get, subject to $Z=0$ in (105),

$$V = \Sigma\frac{Q\sin sx\sin sy}{-\left(\frac{s}{R}\cos sl\right)^2\frac{dZ}{dp}}\epsilon^{pt}, \qquad (111)$$

when x and y are in the first cable; it being v_xv_y that is used in the numerator. Substitute w_xw_y when they are in the Bessel cable, using (110); and v_xw_y or v_yw_x when x or z is in one and y in the other cable. Also, instead of $I_0(q_0z)$, use $J_0(s_0z)$.

When the initial state is given to be that the potential is U, the coefficient of the normal function is got by an integration, thus:

$$A = \frac{\int SUu\,dx}{U-T} = \frac{\int SVv\,dx + \int S_0zWw\,dz}{U-T}, \qquad (112)$$

where in the first form u is the complete normal function, whilst in the second it is separately exhibited for the two cables, the initial U becoming the initial V and W respectively.

§ 326. The above case of two cables of the ordinary kind having different uniform resistance and permittance, and more particularly the case in which one cable is uniform whilst the other is of a variable type, are meant to lead easily to a broad understanding of a normal distribution in general. It should be regarded as a single function of position in the combination, no matter how many forms it may assume in different parts. To illustrate this, imagine any number of cables put in sequence, with any terminal arrangements, any way of variation of resistance and permittance, and any number of intermediate insertions or leaks. A normal system of potential is one which, when left to itself, preserves its form when subsiding. To find it, we may first divide the whole cable into sections containing no intermediate insertions or leaks. Then, if R, S vary in any section according to a single formula, it may be treated by itself. But if there are two or more formulæ concerned, we must subdivide into smaller sections. So we come down to a section having a single characteristic. It is equation (95) above. Regarding p as a constant, there are two independent solutions, say $u=av+bw$, a and b being any constants, v and w the two solutions, functions of x. Every section has its u of this kind, with its own special v and w. They have next to be fitted together. This is to be done by the intermediate and the terminal conditions, introducing all the necessary continuities and discontinuities. The result is a single normal function u, represented by u_1 in the first section, u_2 in the second, and so on, but of arbitrary size. At the same time the conditions furnish a general determinantal equation. It is the characteristic of the whole combination, say $Z=0$, and the values of p satisfying it are *the* values of p permissible. Thus $Au\,\epsilon^{pt}$, where A is a constant, represents a complete normal system at time t, so far as the cable is concerned, and

Digitized by Google

therefore $\Sigma A u \epsilon^{pt}$, including all the normal systems corresponding to the different p's, represents the solution arising from any initial state. The normal u may, if we please, be continued over all the intermediate and terminal insertions and leaks, to make it fully complete. The size of the normal systems is then settled by their conjugate property, which leads to the formula (62), and other forms. If any part of the combination contain no energy initially, its detailed consideration may be omitted, and its influence on the rest allowed for by a resistance operator. This applies to parts of the cable itself as well as to insertions and leaks.

(To be continued.)

CABLE COMMUNICATIONS WITH SOUTH AFRICA.

In consequence of recent events in the Transvaal, and the delay which has occurred to ordinary telegrams between that part of the world and Europe, much interest has been naturally shown in our cable communications with South Africa. The following statement may serve to remove much of the misapprehension which appears to exist on this subject. The present submarine connections, under normal conditions, with South Africa are as follows:—

The original cables on the East Coast, starting from Aden, where they join the Eastern Company's system of duplicate and triplicate lines to this country and the East. The sections are: Aden to Zanzibar, Zanzibar to Mozambique, Mozambique to Delagoa Bay, and Delagoa Bay to Durban, where they connect with the Government land lines communicating with the interior of South Africa and Cape Town. There are two cables between Zanzibar and Mozambique, and the East Coast lines are all provided with apparatus for duplex working.

From Cape Town the West Coast cables establish communication with England by way of Mossamedes, Benguella, Loando, Accra, Sierra Leone, St. Vincent, Madeira, Lisbon to the Land's End. From St. Vincent to Lisbon the cables are duplicated, and from Lisbon to the Land's End there are three submarine lines. It will be seen therefore that, starting from Lisbon, there is a complete telegraphic circle, forming two alternative routes, round the continent of Africa.

On Tuesday, December 24th, the cable between Aden and Zanzibar became interrupted, and at this time the Eastern Telegraph Company's cable steamer "Chiltern" was two days out from Suez on her way to Aden, where she arrived on the Friday night, and found a telegram awaiting the ship's arrival instructing her to proceed to the repair. Having coaled with all despatch, she left on Saturday evening for the position of the break, which was caused by suspension across a submarine valley. The interruption of this cable, it will be observed, was prior to the outbreak of hostilities in the Transvaal, and before any information that they were probable had reached this country. Notwithstanding, however, that the Company had no reason to apprehend any unusual pressure upon their cables, the Eastern and South African Telegraph Company, in order to save the six extra days which it would have taken their own repairing steamer, the "Great Northern," then at Cape Town fully manned, to restore the communication, chartered at considerable expense the s.s. "Chiltern." On the following Thursday, January 2nd, the ship arrived in the neighbourhood of the fault, fulfilling anticipations almost to an hour. With the second sweep of her grapnel she hooked the Aden end of the cable, and proceeded to pick up the fault. The end was then buoyed, and she proceeded to grapple for the Zanzibar end, which she was successful in securing at the first attempt. The necessary tests having been effected, the final splice was made, and the cable dropped into its position at 7 p.m., London time, on Saturday, January 4th.

Meanwhile, in addition to heavy traffic in connection with the Ashantee expedition, events had arisen which are too well known to need recapitulation, which flooded the remaining line of communication, viz., that by the West Coast, with Government telegrams sufficient to tax the cables to their utmost capacity, and as it is a provision of the International Convention that such traffic should take precedence of all other telegrams, it necessarily followed that Press and ordinary messages were excluded until the line was completely clear of official despatches. The first telegram containing information of the events alluded to was handed in at the Cape Town office on December 30th, and from that day until January 4th, when the East Coast connection was restored, not a single ordinary telegram, either Press or commercial, left South Africa for Europe of later date than December 30th. The restoration of the East Coast line, in any case, would have afforded immediate relief to the pressure; but, as hostilities had ceased, the Government traffic was not so heavy, thus affording a double relief to the West Coast route. Owing to arrangements made in London, by which the different routes were judiciously utilised, the block of nearly a week's traffic from and to the Cape is now practically cleared. There has not, however, during the whole period, been the slightest delay on the messages of any Government, British or otherwise. It should be distinctly understood that the submarine companies are only responsible for delay upon messages received at their offices on the seaboard, the land lines in this case being solely controlled by the governments of the Transvaal and Cape Colony.

It should be borne in mind that the carrying capacity of every cable is strictly determined by the size of its conductor and its length, and allowing for the comparatively slow rate at which long submarine cables must of necessity be worked, it does not require much calculation to see that the unusually heavy Government traffic could not fail to cause considerable delay to ordinary messages. And obviously cable companies cannot be expected to expend millions of money in laying triplicate lines to provide for a contingency which may only occur once in a generation, and which was caused in this case by the most inopportune interruption of one of the existing lines of communication.

The existing cables have a great reserve of carrying capacity over all ordinary traffic, and no delay was caused by the abnormally heavy telegraphing recently in connection with South African mining.

Centralisation of Light, Power and Traction in Germany.—At a recent meeting of the Elektrotechnischer Verein of Berlin, Dr. M. Kallmann, electrical engineer to the municipality of Berlin, read a Paper on the centralisation of the supply of light, power, and traction. He showed by means of statistics, and diagrams representing the average figures of seven provincial supply stations in Germany, that it would be of great advantage to the electric light stations if the supply of power for motor and traction purposes was carried out by lighting stations. In provincial towns little has been done in this direction, but in Berlin there are at present about 700 motors of a total capacity of 2,500 H.P. connected to the different central stations. The energy consumption of these motors during last year was a little over 1,000,000 kilowatt-hours. This is about 16 per cent. of the year's output of the stations. Dr. Kallmann then touched on the economic aspect of the question. It is the practice of Germany to connect in continuous-current plants two 275-volt dynamos to each steam engine, which can then either be connected in series, making 550 volts for traction work, or run in parallel for lighting purposes on the three-wire system. Such arrangements permit of the alternative use of the sets for either traction or lighting purposes, and each set may also serve as reserve to the other. Such a combination will be put to a practical test in Berlin in 1896, when two electric tramways, which are now being built to connect the city with the Industrial Exhibition at Treptow, will be supplied with current from the lighting stations. The charge is fixed at 1·2d. per kilowatt-hour, and it is estimated that the year's consumption of each line will be over 1,000,000 kilowatt-hours. If the Berlin tramways, with their 210 miles of line and 19,000,000 car-miles per annum, were electrically equipped, and assuming the traffic to increase to 25,000,000 car-miles per year, the total year's consumption would be over 20,000,000 kilowatt-hours, which would be three times the present total output of the Berlin stations.

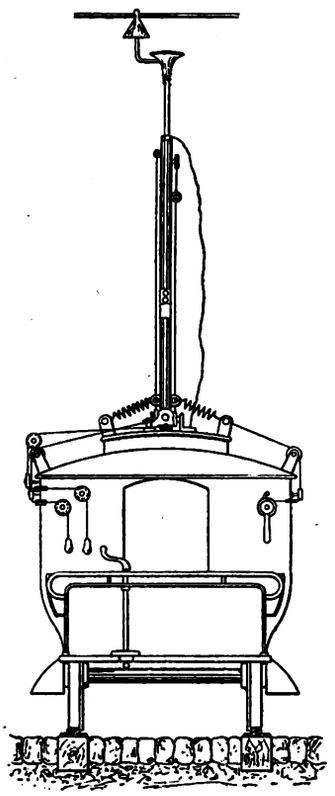
THE WESTINGHOUSE SIDE-CONTACT TROLLEY WHEEL.*

The trolley and its accessories have given rise probably to as many modifications as any one of the other numerous details which go to make up the electric railway system of to-day. Early work began with the over-running trolley, which, however, was soon found to be ill adapted to the task, and hence was soon followed by the under running contact, which is at present in universal use. Like many devices of the kind in electrical work which have proved successful, the under-running contact has given rise to litigation, and inventors have been at work to devise other adequate and practical means. A recent striking example of this is exhibited in a patent issued to Mr. George Westinghouse, Jun., which describes a trolley designed to make contact with the side of the trolley wire.

The accompanying illustration shows the method. As will be seen, the trolley wheel, if it may be so designated, is of a tapering



Westinghouse Side-Contact Trolley wheel.

inverted bell form, having a wide flange which extends above the top of the trolley wire. The trolley pole on which the wheel is mounted swings in a plane at right angles to the direction of the car, so that it is always pressed toward the side of the wire. The arrangement is such that by suitable springs the wheel can be made to effect contact with either side of the wire. Suitable arrangements also provide for variations in the height of the wire. The tension of the springs controlling the contact trolley is effected by cords under control of the motorman.

DEVICE FOR PROTECTING PHYSICAL INSTITUTES AGAINST DISTURBANCE BY ELECTRIC RAILWAYS.†

BY DR. O. FRÖLICH.

In the *Elektrotechnische Zeitschrift* of July 4th, I made two proposals by which measuring instruments in physical institutes could be protected from the disturbances caused by the earth return of electric tramways. The principle was one of compensation, and consisted of wires in which flowed either part of the earth current or a shunt current appearing at the same time as the earth current, the wires being led over or around the instruments intended for protection in such a fashion that the immediate action of the earth current would cancel itself. In the first proposal the compensation wire or wires terminated in earth plates which were buried near the building intended for protection, and which received part of the earth current. In the second proposal the compensation wire was connected to several points of the rails near the institute, then led over the building and connected to the end of the rails near the power house. The first proposal was intended to compensate all earth currents passing under or near the building, and the second only the leakage from the tramway. The second proposal had the advantage over the first, that earth plates and the difficulty connected with them were avoided and only metal conductors were employed. Without, however, dropping the first proposal, I thought it was more profitable to work out the second and bring it into a practical shape. I have been successful in attaining this aim, and the disturbances due to electric lines have been reduced 75 per cent. to 80 per cent. on one line, and 95 per cent. on another. In a small model a 95 per cent. reduction was obtained. The first experiments were made by Dr. Raschorn on the Steglitz-Lichterfelde and Dresden-Blasewitz electric lines, but as far as compensation is concerned, no practical results were then obtained, and it is therefore unnecessary to describe these experiments. To solve the problem on an actual line was a difficult matter, as only a few hours during the night were available. As, therefore, the method of experimenting was likely to want remodelling and correcting, a small model of an electric line was put up, and so arranged that a magnet needle placed near indicated any disturbance when the model car was on the line. The disturbance curve for every position of the car was first traced out, and the compensation wires then arranged accordingly. As it has been found that the so-called stray earth currents are the main cause of the disturbance, and the direct effect of the conductor of the tramway disappears as compared with the action of the earth currents, the model line was arranged accordingly. A curve such as T, in Fig. 5, was then obtained. When a car leaves the generating station a disturbance is noticeable as the car approaches the instrument; this disturbance increases slowly at first, then more quickly, and continues to increase until the car has left the instrument a certain distance behind; it then settles down to a constant amount until the car has arrived at the far end of the line. This typical course of the disturbance represents the case of a straight tram line running parallel to the needle, but is modified when the line has curves, and is in a different direction to the needle. In reality, however, these modifications do not appear to be very important, at least when needle and line are in the same direction. Curves have been traced for the lines at Dresden and Pankow. It will be observed that the main action of the earth currents commences when the car has passed the instrument. Earth currents mostly appear near the parts of the rails in which a current is passing, and they persist until the car is at a great distance. Disturbances caused by direct influence exhibit a different course to the earth currents. While the latter act mainly upon the instrument when the car passes, and for a certain time afterwards, the direct action behaves like a powerful but short magnet which moves behind the car at a lower speed. By Ampère's law the rectangle which is formed by the overhead conductor, the corresponding part of the rails, the conducting parts of the car and the conductor between generator and overhead wire, can be replaced in its action upon the instrument by a magnetic double plane, which, however, again can be replaced by a short magnet, the axis of which is perpendicular to the tram line, and which lies in a certain central portion of that plane, the magnetic intensity of which increases with the length of the rectangle—that is to say, with the distance of the car from the generating station. The conductor rectangle grows steadily with the movement of the car, and and while one of the short sides remains stationary at the generator, the other formed by the car moves over the line. The magnet representing the conductor rectangle is situated near the geometrical centre of the rectangle, but its exact position depends upon the position of the instruments. When the car travels over the whole length of the line this magnet will only go as far as the middle of the line—that is to say, it only moves at about half the velocity of the car. The course taken by the action of this magnet on the instrument depends largely on the position of the instrument and the direction of the needle, but will not be further investigated here. Except when the instrument is quite close to the line, the influence is considerably weaker than the influence of the earth current.

From Fig. 1, in which O O′ represents the overhead conductor, S S′ the rails, G the generator, and W the car, it will be seen that the current coming from the car does not return only by the rails behind the car and the earth near them, but returns also partly through the rails in front of the car and the earth to the generator. This is mostly the case when the rails are in a bad condition, and the consequence is that the influence of the earth current appears in advance of the car, and the effect may have been reversed before the car has passed the instrument. The disturbance curve shown in Fig. 7 was observed on the Dresden-Blasewitz electric tramway, and shows at the beginning a negative deflection, which was very likely caused by the earth currents being in advance of the car. It may be possible that the types of disturbance curves already

* From the *Electrical Engineer* of New York.

†Abstract of a Paper read before the Elektrotechnischer Verein of Berlin.

Digitized by Google

obtained are not the only ones, and further investigation may increase them; but practically it may be taken that in most cases the earth currents are the main cause, and the typical curve is practically that represented in Fig. 5. Other causes than earth currents will only modify the curve, but will not essentially alter it.

Let us now consider the compensation curve. As this is required to abolish the disturbance, arrangements must be made that the compensation curve is as similar as possible to the disturbance curve in size and shape. The question is whether this was attained in the first proposal, and if not how the compensation arrangement has been modified.

Let us assume that the current in the rails is only flowing between car and power house—that is to say, behind the car. In reality, as we have seen, current flows also in front; the current flowing behind forms, however, the main part, and assuming this condition, the nature of the problem appears at once. Further, we will assume that the current in the car motor as well as the current in the rails always remains constant. Let us consider at first the case of the first idea, which is represented in Figs. 2 and 3. O O′ is the overhead conductor, S S′ the rails, G the generator, A′, A, A″

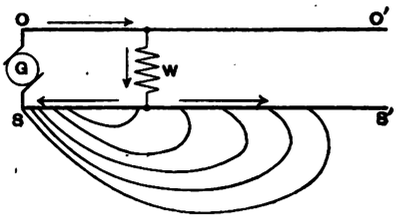


Fig. 1.

the points where the compensation wire is connected to the rails, J is the physical institute, and U the windings which are laid round the institute for the purpose of compensation. The other end of the compensation wire is connected to the rail ends at the power house. I have assumed that current is flowing only in the conducting parts between car and power house. As the points of connection, A′, A, A″, act very much like one point, say A, I will assume that this latter only exists. Then a potential difference will prevail between the contact point of the car and S, but none between the former and S′. In the circuit S, A, U, the potential difference between car and the rail ends at the power house acts as an E.M.F. This will increase as the car moves along until it reaches the point A. During the movement of the car from A to S′, however, the potential difference remains constant. If the curve of the compensation current is set out, a line, K, will be obtained, as in Fig. 3. On comparing this curve with the disturbance curve T (Fig. 5) it will be observed that there is only an approximate agreement when

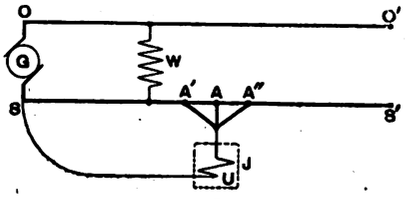

Fig. 2.

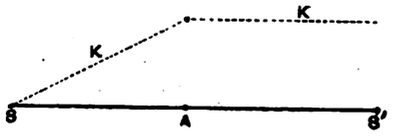

Fig. 3.

the institute happens to be so near to the power house that the disturbance commences immediately the car leaves the latter. The further away the institute happens to be from the power house the less the two curves of disturbance and compensation coincide, and the less the compensation of disturbance. The earlier proposal, therefore, does not offer the right solution of the question.

Let us now alter the arrangement so that the compensation circuit is not connected to the rail-end at the station, but to the points A and B of the rails (Figs. 4 and 5). No current will enter the "loop circuit" until the car has arrived at A, but then it rises evenly as far as the car position B, after which it remains constant. The compensation obtained in this case is shown by K, K in Fig. 5. The "loop-circuit" must be so adjusted that in the middle between A and B the disturbance and compensation current act equally in opposition to each other upon the needle of the instrument.

The disturbance curve is not always of the shape assumed in Fig. 5, and if the physicist wishes for the entire removal of the disturbances, arrangements must be made so that the compensation curve imitates the path of any given curve as closely as possible. This can be achieved by the use of several compensation circuits. Let the disturbance curve, for instance, have the shape T, T in Fig. 7, which consists of a negative dip, a positive rise and a positive fall. We replace this curve by the dotted line K, K, which consists of the straight lines A B′, B′ C′, C′ D′. We shall have to lay a corresponding compensation circuit round the instrument (*see* Fig. 6), and select the points of connection A, B, C, D in such a way that they correspond to the abscissæ of the corners A, B′, C′, D′. The windings U form a continuous circuit, certain points of which are connected to the rails.

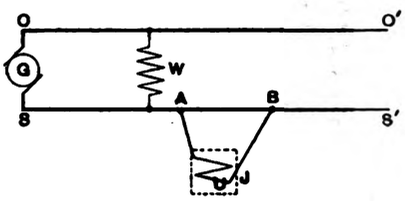

Fig. 4.

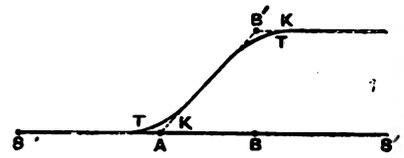

Fig. 5.

The adjustment is carried out in the following way: The circuit is switched in and then so adjusted that when a car is in a position between A and B, the compensation current acts in exactly the same way as indicated by the line A, B′. If no other loop circuit were provided, the compensation current would keep the value of B′. The car is now given a position between B and C and the circuit B, U, C is switched in, without the circuit U, A, B being cut out, and the former is so adjusted that the effect equals the disturbance, or the value indicated by the line B′, C′. If, then, the car runs beyond C, the effect of compensation would retain the value C, C′ if no other circuits were switched in, and would thus differ from the disturbance curve. In consequence the circuit C, U, C′ is switched in while the other circuits remain still in

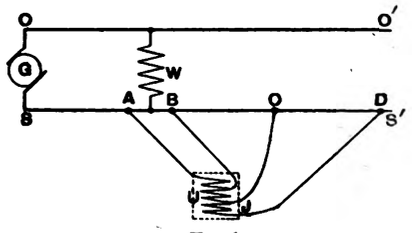

Fig. 6.

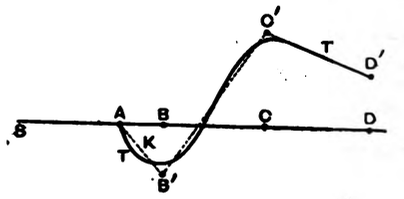

Fig. 7.

action, and is so adjusted that if a car is between C and D the compensation indicated by C′ and D′ is obtained. In this way the compensatory action follows the broken line A, B′, C′, D′, and represents within a certain degree the disturbance curve. The switching in of the compensation circuits, therefore, annuls the disturbances to within a small amount, which can be regulated by the number of circuits employed.

Let us now consider the properties of the compensation arrangement. The question is first whether the variation of the current in the car has any influence on the correctness of the compensation. But consideration will show that the amount of current has no influence on the compensation arrangement. For instance, a disturbance curve for 100 amperes will be very similar to one for 50 amperes, only the scale for the ordinates has to be altered. The amount of the main current has therefore only influence on the balance of disturbance not compensated. The ratio of the balance to the main current remains always the same. It follows

Digitized by Google

that the compensation takes place in a percentage ratio—that is to say, for every current value a certain percentage of the disturbance is annulled and a certain percentage of it remains. The number of cars and their positions are of no importance to the compensatory action. If the compensation is so arranged that a car can run over the whole line with different current values without creating important disturbances, it seems clear that any number of cars can run with the same effect either in the same or opposite direction. Of course, the unbalanced disturbances will increase in proportion to the number of cars. The trace of the tramway cannot make compensation impossible, but may perhaps cause some difficulty. A complicated trace produces a complicated disturbance curve, and more compensation wires are required ; but the greater part of the disturbances can always be got rid of. This kind of compensation has the advantage that it not only influences the disturbances caused by earth currents, but also such as are caused by the effect of the loop, the direct effect of the conductors, and the magnetism of the car motor. Therefore, the institute to be protected can be quite close to the power house—the compensation will still retain its efficiency. The peculiarities of the building must, of course, be taken into consideration. When compensating arrangements are put down care must be taken that the windings are in the proper direction.

Details of the experiments on the lines at Dresden and Pankow I shall make public on a later occasion, but I may state here that with one loop circuit on the first-named line 75 to 80 per cent., and on the last named with three circuits, 95 per cent. of the disturbances was annulled. Herr Ulbricht has proposed to connect the loops not to the rails, but to the overhead conductors. This alteration would simplify the adjustment, as in a overhead conductor there is scarcely any "forward" current. No great objections exist to the adoption of this proposal.

For actual application there are two systems from which to select, viz., compensation of the whole building by means of coils round it, and compensation of each individual instrument by means of a set of coils. The first method possesses the advantage that the instruments are kept free from additional wires, but has the disadvantage that the compensation is only perfect in the middle of the building, and rather defective near the walls. The second method, however, gives good protection to all instruments, but necessitates a certain complication, as each instrument has to be provided with a compensation arrangement. Both systems are to be put to a practical test on the Pankow line shortly, but it can already be predicted that single protection is preferable. With regard to the cost of such a compensatory installation, I do not think that it will amount to £500.

ELECTRIC MOTORS IN GOLD AMALGAMATING PLANT.*

A somewhat unique application of electricity, and one of interest to the mining industry, has recently been made in the adaptation of electric motors to the operation of a Bennett amalgamator. The amalgamator consists essentially of the following parts :—A truck and frame for supporting the larger part of the machine—arranged to be run forward on a track as the work progresses ; a turntable supporting a boom and dipper ; the boom and dipper for excavating the dirt, and a revolving cylinder or screen with a hopper. Into this the earth is thrown from the revolving screen, the finer material passing through into the amalgamator, the coarse material being discharged at the end of the drum into the tailings carrier.

The amalgamator is a large trough in which the fine material, after passing through the screen, is amalgamated. In the bottom of the amalgamator is an agitator, moving backwards and forwards to keep the material well stirred up, and a wheel for raising and discharging the fine tailings after the removal of the gold.

The four motors used in operating this machine are so constructed as to be thoroughly protected from water or dust. One of these motors is mounted on the frame of the machine between the turntable carrying the cab and the revolving screen. It is geared to a shaft connected by a sprocket chain to the revolving cylinder, the tailings carrier, the agitator in the amalgamator and the wheel for discharging the tailings at the outer end of the amalgamator. A clutch is provided to throw it into gear with the trucks for moving the entire machine backwards and forwards.

The second motor is placed in the cab and operates the dipper by means of a fine-wire rope passing around the drum to which the motor is geared.

The third motor is mounted on the dipper boom, and is geared to a drum placed just above it. Fine-wire ropes pass around this drum, and are attached to both ends of the dipper handle. The dipper may thus be thrust out or in according to the requirements of the work.

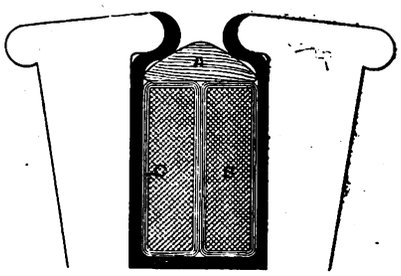
* Abstract from the *Electrical Review* of New York.

The fourth motor occupies a place in the cab, and drives, by means of a bevelled gear and large sprocket chain, the turn table. This motor is also used to swing the dipper boom around from the front of the amalgamator to a position which allows of the dirt being thrown into the hopper of the revolving screen. The motor operating the cylinder, the tailings carrier and the agitator in the amalgamator runs continuously when the machine is in operation, and is provided with a simple starting rheostat only. The other three motors are controlled by reverse rheostats in the cab, and are handled by one man.

A 1,500 KILOWATT RAILWAY GENERATOR.

A good example of recent American practice in railway generator construction is afforded by a 1,500-kilowatt machine, which is now being built for the West End Street Railway Company, of Boston. The armature core of this generator is built directly upon the shaft of an Allis cross-compound engine ; the shaft is 2ft. in diameter, and weighs something over 60 tons. The diameter of the armature is 10ft. 6in., and its weight, with commutator, approximately 40 tons.

The armature core is being wound while in position on the shaft. The core is built up of nine lammelar sections separated by eight brass spiders, leaving ventilating apertures at those points ; each section contains about 210 sheets of soft charcoal iron. The core is provided with 696 slots, each of which contains two copper conductors insulated from the slot and from each other. The conductors are firmly locked in the slot by driving in a long wooden wedge above them, and the slots are liberally lined with fuller board and mica before the insertion of the bars, which are individually insulated with tape and mica, as shown in the accompanying diagram.



The rectangular copper bars are $\frac{1}{4}$in. by $\frac{3}{4}$in., and are fastened to the connectors by a copper clamp, the joint being afterwards sweated with solder. The peculiar shape of the armature tooth renders it next to impossible to dislodge a conductor either by magnetic drag or centrifugal force.

The spiral method of connection is used on this machine. The bars are usually inserted carrying the front connector already soldered on, and the rear connector is attached after the bar has been locked in position. The machine has 12 poles, and therefore the connectors partake very little of the spiral form, being only slightly curved. Two weeks are needed in which to wind the armature, one of which is required for preparing and insulating the grooves. The clearance of the armature will be about $\frac{1}{4}$in. The armature is multiple-wound, and 12 sets of brushes are to be employed. The field-magnet is to be of cast steel. The commutator is 20in. across the face and 7ft. in diameter.

The set is interesting from a mechanical as well as an electrical point of view. The Allis cross-compound engine takes steam at 180lb., and expands in two cylinders 32in. and 62in. in diameter respectively. The stroke is 60in. and the speed 75 revolutions per minute. The 73-ton flywheel is 24ft. in diameter and therefore has a circumferential speed of 5,655ft. per minute. It is substantially built to withstand this stress, being made up of 19 1in. wrought-iron plates. The second and the eighteenth plates form webs going clear to the hub. The wheel is fastened together with 128 $1\frac{1}{4}$in. iron rivets, and is composed of 69 web sections.

Electrical Mining Plants.—Messrs. Siemens and Halske have recently secured a contract for an electric boring plant for the State salt mines at Hallein. The plant will comprise a high-pressure turbine coupled direct to a continuous-current dynamo and two boring machines. The Gerhard Stone Coal Mining Company has recently put down a new ventilating plant at its Rammelt pit at Luisenthal. The plant is interesting from the fact that it is the first of the kind to be operated by electricity in the Saarbrücken mining district.

CORRESPONDENCE.

THE AUDIT OF ELECTRIC LIGHT COMPANIES' ACCOUNTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The correspondence between the Institute of Chartered Accountants and the Board of Trade with reference to the audit of Electric Light Companies' accounts opens up several very interesting questions.

It is not, perhaps, generally known that there is no enactment in the Companies Acts requiring an audit of a limited company's accounts, except in the case of a banking company registered after August 15, 1879, as a limited company. It is true that the specimen form of articles given in Table A of the Companies Act of 1862 provides for an audit, and that it is most unusual for any company to dispense with provisions in its articles requiring an audit, but an audit is not made obligatory by Act of Parliament.

By Section 9 of the Electric Lighting Act of 1882 it is provided as follows:—

"9. The undertakers shall, on or before March 25th in every year, fill up an annual statement of accounts of the undertaking made up to December 31st then next preceding, and such statement shall be in such form, and shall contain such particulars, and shall be published in such manner as may from time to time be subscribed in that behalf by the Board of Trade."

And the model form of Provisional Order provides as follows:—

"8. The annual statement of accounts of the undertaking before being published, as provided by Section 9 of the Electric Lighting Act, 1882, shall, so long as the local authority are not the undertakers, be examined and audited by such competent and impartial person as the Board of Trade shall appoint, and the remuneration of the auditor shall be such as the Board of Trade shall direct, and the same and all expenses incurred by him in or about the execution of his duties to such an amount as the Board of Trade shall approve shall be paid by the undertakers on demand, and shall be recoverable summarily as a civil debt.

"The undertakers shall give to the auditor, his clerks and assistants access to such of the books and documents relating to the undertaking as shall be necessary for the purposes of the audit, and shall when required furnish to him and them all vouchers and information requisite for such purpose, and shall afford to him and them all facilities for the proper execution of his and their duty.

"The Board of Trade may make and vary regulations prescribing the times at and the mode in which such audit shall be made and conducted or otherwise for the purpose of giving effect to the provisions of this section.

"Any report made by the auditor, or such portion thereof as the Board of Trade shall direct, shall be appended to the annual statement of accounts, and shall form part thereof for the purposes of the said Section 9."

There is no clause similar to Section 9 of the Act of 1882 in the Gas Works Clauses Act or in the Railway Clauses Act, and the Companies Clauses Act of 1845 merely provides for the election of auditors *by the Company*, except where, by the Special Act, auditors shall be directed to be appointed otherwise; and these auditors are directed to examine the accounts, and either to make a special report on the accounts or simply to confirm the same, such report or confirmation to be read with the report of the Directors at the ordinary meeting.

On the other hand, the Metropolis Water Act of 1871 provides that every company for the time being supplying water for domestic use within the limits of the Act is to forward to the Board of Trade and certain other authorities a statement of account in such form and giving such particulars as may from time to time be prescribed by the Board of Trade, and there is to be an auditor from time to time appointed by the Board of Trade.

Section 40 of this Act provides as follows:—

"40. The auditor shall once in every half-year audit the accounts of the companies.

"If he finds the accounts correct he shall certify the same; but if in any instance he finds the accounts of any company incorrect in principle or in detail, he shall require such company to correct such accounts in such manner as he thinks right, and no future dividend shall in any case be declared by any company until their accounts are certified by the auditor, provided that the suspension of a dividend under this section shall not operate until after the expiration of nine months from the date of the audit."

But any company thinking themselves aggrieved by any Act or determination of the auditor can, under Section 42, bring the matter to arbitration.

Now it will be noticed that there is a great deal of difference between the provision for the annual statement of accounts to be made to the Board of Trade under the Electric Lighting Act, even when coupled with the audit clauses of the Provisional Order, and the provisions of the Metropolis Water Act of 1871, under which power is given to the auditor to require a company to *correct* any accounts which he finds incorrect in principle or in detail. And I submit that the audit of an electric lighting company's accounts by the Board of Trade is merely made for the purpose of obtaining independently statements as to the expenditure and as to the application of revenue with a view to the special provisions of the Act and Provisional Order, and particularly with a view to the anticipated purchase by the local authority at the expiration of the statutory period, and that the Board of Trade auditor has no power to direct such a company to alter its accounts in principle or in detail unless he can show that the Company has committed a breach of the terms of the Electric Lighting Acts or Provisional Order.

The letter from the Board of Trade recently published states, as I claim in support of this suggestion, "That the Board of Trade audit is of a different character to that of a shareholders' audit, and has in view different objects." Moreover, *there is no audit clause in the model Provisional Order, the "undertakers being a local authority."*

Now the object for which the shareholders' audit is made is that as between the Directors and the shareholders it shall be shown that capital is not paid away in dividends, that all payments are duly vouched and all receipts duly entered, and proper provision made for bad debts or contingent liabilities, and, in fact, that the accounts are properly kept, having regard to the constitution of the Company. If the above suggestions are correct, the importance will at once be seen of drawing the line between the two audits, and limiting the rights of each auditor to interfere in the management of the accounts to the special provisions under which his appointment is made. If this is not done, each auditor may by degrees get into the way of directing, not only how the accounts shall be kept, but also what amounts are properly chargeable to capital and revenue respectively, and if they do not take the same view very serious difficulties may arise; whereas if, as I submit, the duties of the Board of Trade auditor are limited to ascertaining and seeing that the provisions of the Acts and Order are duly carried out, while the shareholders' audit deals with matters arising out of the special constitution of each company and the proper keeping of the accounts, there need be no difficulty. But I do submit that there is this distinction, and that it should be carefully observed.—Yours, &c.,

SYDNEY MORSE.

4, Fenchurch-avenue, E.C., January 6, 1896.

EARTHED CENTRE MAIN.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In connection with possible dangers from the use of pressure of from 400 to 500 volts on the mains of electrical supply companies, I beg to hand you the following opinion from Mr. Musgrave Heaphy, who has recently discussed this matter with me. I need scarcely state that an opinion from a gentleman with such unrivalled advantages for estimating the dangers of electric power distribution is worth serious attention.

It is commonly assumed in a three-wire system of supply with centre wire earthed that it is impossible for there to be a difference of pressure on any premises, wired on one side of the system, greater than that between one of the outers and the middle wire. Mr. Heaphy points out that the full pressure may be brought into one house under certain conditions.

Assume two adjacent houses, the one connected to the positive and middle wire, and the other to the middle wire and the negative, and let there be in the party wall: (*a*) An iron door frame, wall box, or piece of shafting, &c., communicating between the two houses, insulated by dryness of the wall, by

Digitized by Google

dry woodwork, or other means securing practical insulation; or (*b*) leakage of water into a portion of the wall thus insulated. Assume accidental connection between one of the outer mains, say through a defective flexible wire, and one of the insulated pieces of metal or the damp portion of the wall. The leakage to earth will be probably too small to blow the fuses, and so to disconnect the house. Next assume an accidental leak on the other pole of the system in the adjacent house, say through the metal case of a switch or lamp holder. It is clear that if the piece of insulated wire, or damp wall, be touched at the same time as the defective fitting, that a shock due to the full pressure will be felt.

These conditions are not likely to occur often, for two earths on opposite poles have to be made concurrently and in adjacent houses. Yet the risk is increased by the consumer's difficulty in detecting either leak except by a shock.

An obvious safeguard is to earth all isolated pieces of metal; but this does not get over the risk from walls which are damp locally. Iron barrel or concentric wiring, with the outer earthed, appear to be the safest method of wiring under the conditions assumed. For, with either it is probable that a single leak would blow one of the fuses, and thus call attention to the defect. In fact, if the middle wire be earthed all iron-work in buildings should be effectively earthed also.—Yours, &c., ALBION T. SNELL.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think Mr. Campbell-Swinton's views and my own are very little at variance, and I desire to add to my communication of last week my hearty approval of his ninth proposition—viz., the establishment of a class of associate members with corporate privileges similar to that in the Institution of Civil Engineers, in which gentlemen who may not be thought qualified for full membership may be placed, the present associate class being retained for outsiders whom it is to the interest of the Institution to include in its ranks and who wish to be included.

From correspondence that has reached me, I gather that there is a very strong feeling among men who have done good service in the cause of electrical science, but who have been denied the privilege of full membership, that at present they hold no better standing in the Institution than the man who holds shares in an electrical company does.

I think it should not be forgotten, also, that electrical engineering is different from every other branch of engineering. A man can hardly be an expert in bridge building, for instance, unless he gets his living by it; but many men are experts in electrical engineering, and have done important work, not because they were obliged to do the work, but almost entirely because they were not—because they had money to spend.

To take a case in point. Sir David Salomons' work on the accumulator can hardly be regarded as other than valuable, and it can hardly be doubted that its value was greatly enhanced by the absolutely independent line his position enabled him to take.—Yours, &c., SYDNEY F. WALKER.

Cardiff Electrical Works, Severn-road, Cardiff.

IMPORTED INCANDESCENCE LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great interest the article in your issue of the 3rd inst., based upon the "Report of a Committee of Representatives of German Electric Supply Undertakings." I quite endorse the opinion expressed at the outset that the glow lamps in the market are not, according to quality and life, all that could be desired. But it is regrettable that it should obtain in our own market to an equal, if not to a greater extent than appears to be the case in Germany. But the results of recent tests prove the English-made lamp to be superior to those imported from abroad, and it is obviously unfair that such inferior goods should be placed in open competition upon our markets, without test, guarantee, or warranty of any kind. The shapes marking the general conformation of these foreign-made lamps are so nearly approximate in every detail that the ordinary consumer or purchaser cannot note the difference, since it appears by your article that the general public cannot detect the photometrical difference between an 8, 16 or 20 c.p. lamp, even when these are disposed among others.

Whilst admiring the principle of fair dealing which led to the formation of an executive representative committee, I cannot but hold the opinion that in the first case a very forcible action must have taken place among justly indignant customers abroad, and secondly, that whatever may be the beneficial working result of the Committee in Germany, it will have a very detrimental effect upon our home industries in this direction, since no restriction is placed upon lamps for export, and the ultimate effect of the standardising of foreign-made lamps will be to flood our home markets with the bad ones necessarily rejected.

It is certainly requisite that a purely representative committee, each member to be of sufficiently high professional status, and sequestrated from all commercial influence, should be established for the purpose of standardising the lamps sold in this country. The English makers in this case have no fear, and may safely rely upon the high quality of their goods to realise the best advantage to the consumer.

The tests naturally would limit the variations in photometric value to from 8 to 10 per cent., and above all things, the nominal watts per candle to 20 per cent., relatively to the useful life of the lamp. This, again, should be so regulated that after the period at which the increased absorption of energy has fallen to this degree, the lamp, of whatever type, should be replaced.

British enterprise should by Britons be supported under any circumstances, but when the adverse spirit is represented by the imported scum of the German incandescence lamp mark[illegible], it is time to organise a spirited and strong opposition.—Yours, &c., FREDK. WALKER.

January 7, 1896.

THE THERMOPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In 1887 I constructed and employed for clinical purposes an apparatus precisely similar to that described on p. 285 of your issue for December 27th, and can speak to its efficiency for the measurement of temperature under conditions which preclude the use of other forms of thermometer, its application being almost independent of distance, and covering a wide range of temperature. In one form of the instrument constructed by me small extra resistances were added at each end of the slide wire, the entire length of which then represented temperatures between certain limits (as 90°F. to 110°F.).

In this form the apparatus is capable of giving very accurate measurements.

As you will observe from an inspection of the enclosed patent specification (No. 11042, 1890) it had been my intention to make the instrument self-recording, but unfortunately lack of time has hitherto prevented me from giving the necessary attention to the matter.—Yours, &c.,

47, Russell-road, Kensington, W., C. ASHMORE BAKER.
January 7, 1896.

[We have examined the patent specification mentioned by Mr. Baker, and we concur in his opinion that it describes an invention which is, in general principle, the same as that described in our article of December 27, 1895; although there are some differences in detail. Both inventions depend on balancing two resistances of different metals by means of a sliding contact on a potentiometer wire; that of Mr. Baker would appear to be the earlier of the two.—ED. *E.*]

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is in active preparation, and will be ready at the end of January. Orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. Full particulars post free on application.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES can be obtained of the Booksellers or direct from the Publishing Offices :—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

CORRECTION.—By a slip of the pen in our last issue a Trade Note, referring to the bankruptcy of Messrs. Smeaton and Bennett, electrical and general engineers, of 135, Minories, E., was made to read Smeaton and Page. This has, we learn, caused some annoyance to Mr. Page, who trades under the name of Smeeton and Page, electrical engineers, at 163, Queen Victoria-street, London, E.C. We very much regret that such a clerical error should have occurred, and should have caused Mr. Page any annoyance. The announcement should have read : "Mr. W. Izard, 52, Gracechurch-street, E.C., has been appointed trustee in the bankruptcy of Smeaton and Bennett, electrical and general engineers, 135, Minories, London, E." We need scarcely add that the announcement in no way related to the firm of Smeeton and Page, electrical engineers.

TENDERS INVITED.—The Gas and Electric Lighting Committee of the Wigan Corporation invite tenders for the erection of a dynamo house and boiler house for their proposed electricity generating station. Tenders to the Town Clerk (Mr. J. J. Charnock) by the 20th inst.

——— The Shoreditch Vestry require tenders for the supply and erection of buildings, including engine house, offices and building enclosing dust destructor. Tenders to Dr. H. Mansfield Robinson, Vestry Clerk, Town Hall, Old-street, E.C., by the 20th inst.

——— The National Telephone Company require tenders for larch poles and also creosoted round pitch-pine poles. Particulars from the Stores Department of the Company, Oxford-court, Cannon-street, London, E.C.

——— The Kattowitz Direction of the Prussian State Railways require tenders for the supply of the arc-lamp carbons required for electric lighting purposes on the Kattowitz section of the State Railways. Tenders to the Königliche Eisenbahn-Direction, Kattowitz, Germany, by the 29th inst.

TENDERS INVITED.—The St. Pancras Vestry invite tenders for wiring and other work in connection with the electric lighting of the Vestry Hall and Offices in Pancras-road. Tenders must be sent in to Mr. A. E. Pycraft, at 57, Pratt-street, N.W., by noon of the 16th inst.

——— The Municipal Authorities of Burriana (Castellon) invite tenders for the concession for the electric lighting of the town for 10 years. Tenders to the Ayuntamiento de Burriana (Castellon), Spain.

——— The Roumanian State Railway authorities, Bucharest, invite tenders for the supply of 60,000 rolls of telegraph tape paper for the Telegraph Department. Tenders by the 23rd instant.

TENDERS ACCEPTED.—The Loughborough Town Council have conditionally accepted the tender of the Brush Company for the supply of the necessary plant for the electric lighting of the sewerage works.

——— The Walsall City Council have awarded the contract for wiring the Free Library to the Coventry Electrical Engineering Company. The amount of the tender is £140.

TENDERS RECEIVED.—The Chelsea Board of Guardians received 12 tenders for fitting up an electrical wiring installation, with fittings, in the Chelsea Infirmary Extension, Cale-street, S.W. The tenders have been referred to the General Committee for report.

APPOINTMENT VACANT.—The Lighting Committee of the Wolverhampton Corporation invite applications for the post of assistant and draughtsman to the borough electrical engineer; commencing salary £100 per annum. Applications to Mr. F. Harman Lewis (borough electrical engineer), Town Hall, Wolverhampton, by the 23rd inst. Some further particulars are given in our advertisement columns.

DISSOLUTION OF PARTNERSHIP.—Messrs. J. W. Martin and B. R. Fitt, hitherto trading as electric light contractors and ironmongers, at 7, High-street, Grantham, have dissolved partnership. Debts by Mr. B. R. Fitt, who continues.

COMMERCIAL CABLE COMPANY.—We are informed that Mr. G. H. Bambridge has resigned his position as General Superintendent in England of the Commercial Cable Company, and that Mr. Frederick Ward has been appointed manager in England.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MANUFACTURING COMPANY (LIMITED).—This Company have now removed from 109, Farringdon-road, London, to the new address at 186-188, Shaftesbury-avenue, W.C.

BANKRUPTCY DIVIDEND.—A first and final dividend of 6s. 2d. in the £ is payable at 39, York-street, Manchester, on the 20th inst., in the bankruptcy of Dr. J. Whatmough, trading as an electrical engineer, &c., under the styles of D. J. Whatmough, J. and P. Dyer, and lately as W. Mason, at 39 and 41, High-street, Oldham. The bankrupt will apply for his discharge at the County Court, Oldham, on the 22nd instant at 11 a.m.

COMPANY LIQUIDATION.—A notification has been made by the Senior Official Receiver's Office that in future the Press is not to be supplied with copies of Official Receivers' "Observations" on the statements of affairs issued from time to time by the Department in regard to outstanding liquidations. Creditors, contributories and others interested will be considerable sufferers by this decision, and it is to be regretted that such a course has become necessary, as public attention being called to these matters has been of much service in the past.

BRITISH ELECTRIC LIGHT COMPANY, LIMITED (IN LIQUIDATION).—A notification from the Receiver in this liquidation is to the effect that every creditor may write off as a bad debt the amount due to him from this Company, as the Receiver was only able to collect about £10.

ADVERTISEMENTS.—The publisher of *The Electrician* has received several complaints lately from foreign readers that the advertisement pages of the paper have been cut away in order to save postage. This, of course, can only happen where subscriptions are not sent direct from the office. The publisher will be obliged if any subscriber receiving a mutilated copy of the paper will communicate with him, in confidence if necessary. It is a matter of frequent complaint by advertisers that copies of journals sent abroad are mutilated in this way. This can easily happen with papers which are unstitched; and it was this amongst many other reasons that decided the proprietors to make each number of *The Electrician* a compact and complete book.

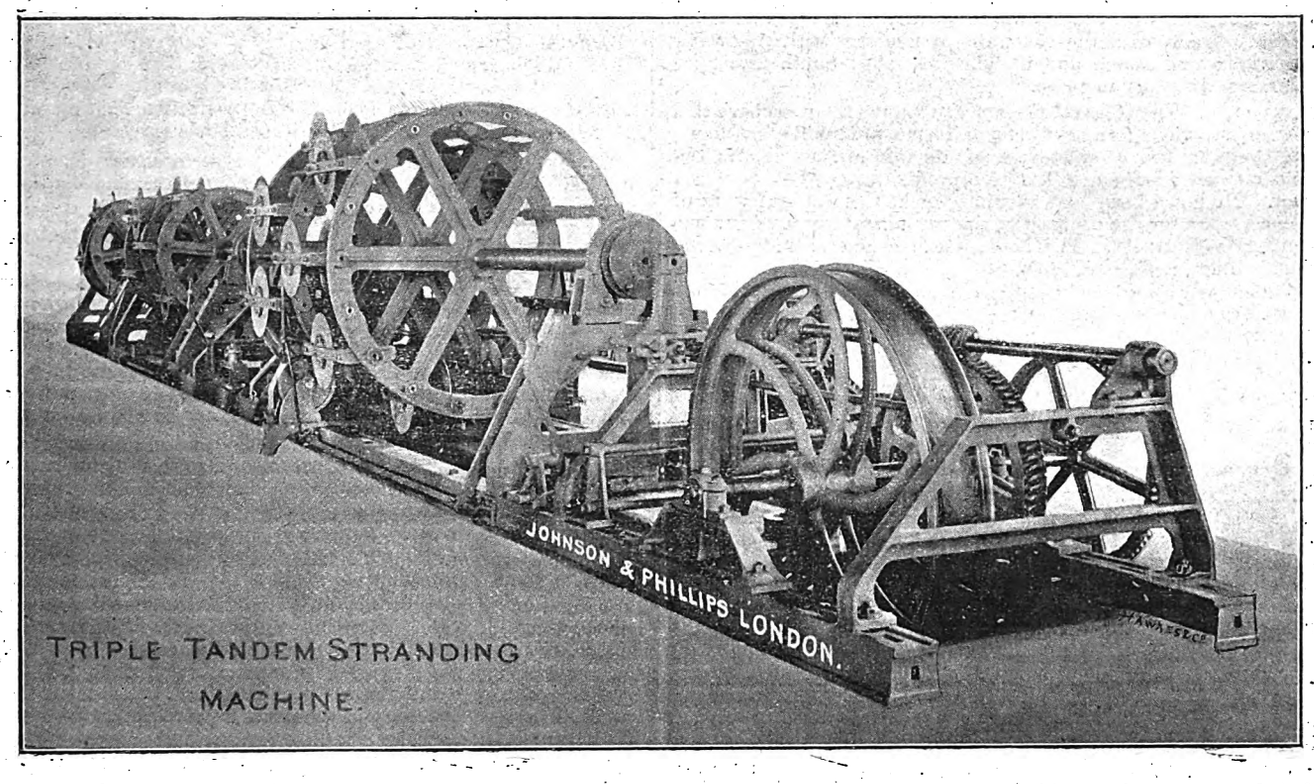
SOCIETÀ ITALIANA GENERALE DI ELETTRICITÀ (SISTEMA EDISON).—This Company has just raised its capital of £144,000 to £360,000 for the purpose of buying up the entire network of tramways at Milan, and equipping and working the same electrically. The new shares have been taken up by a syndicate formed by the Banca Commerciale of Italy.

Digitized by Google

YORKSHIRE HOUSE-TO-HOUSE ELECTRIC LIGHTING COMPANY.—When this Company originally started work in Leeds it was stipulated that a deposit of £1,000 should be made with the Corporation. On the request of the Company the Corporation have decided to return half this amount.

"UNIQUE" SWITCH.—Mr. A. P. Lundberg, of Bradbury-street, Kingsland, London, N., desires us to state that there is no truth in the rumour, which he understands is being circulated, that he is giving up the manufacture of the "Unique" patent switch. All that has happened is that at the request of some of his clients he has reconstructed the "Pioneer" type of switch.

TRIPLE-TANDEM WIRE-STRANDING MACHINE.—The great advance now being made in electric lighting and transmission has made the manufacture of electric cables an important industry. The following description and accompanying illustration of a large wire-stranding machine which has just been completed by Messrs. Johnson and Phillips will therefore be of considerable interest. The machine has been built to the order of a large firm of wire manufacturers on the Continent, and is what is termed a triple-tandem machine, and, as the name implies, consists really of three separate machines arranged "tandem." The first part is a 6-wire machine, the second a 12-wire, and the third an 18-wire machine, each part being arranged so that it may be run in the reverse direction to that of its neighbour, and at a different speed, and thus form a 37-wire cable in one operation. The centre wire being led through the centre hollow shaft, the first part of the machine lays six wires round it, forming a 7-wire cable; the second part lays 12 wires on this, forming a 19-wire cable, and the third part lays 18 wires over all, making up the 37 wires. The machine will equally well make cables with a lesser number of single wires, or if a flexible cable is required 37 strands made up of smaller wires can be used. The machine is also so arranged that each part may be run in the same direction and at the same speed, and provision is made for leading the wires from the first and second parts through the third, so that the whole of the 37 wires or any lesser number may be laid on a cable in one flake, as might be required, for instance, in the manufacture of a concentric cable. This also adapts the machine for making a much larger cable. For instance, if the 37-wire cable is passed through the machine again and covered with 24 wires, a 61-wire cable is formed; this passed through again and covered with 30 wires forms a 91-wire cable, and this, in turn, can be passed through and covered with 36 wires, making up a cable of 127 wires. The bobbins each hold about 3cwt. of wire, and are suitable for all sizes up to No. 6 B.W.G. All twist is kept out of the wires during the operation of cabling by means of the usual arrangement of cranks and eccentric rings. The ground space covered by the machine is 60ft. by 10ft., and it is erected on a continuous cast-iron girder bed running along its whole length. As will be seen on looking at the illustration, the draw drums are of large diameter, and they are driven by means of worm gearing, the speed being capable of considerable variation by means of change wheels to give the different lengths of "lay" for the wires. The various parts of the machine are driven from a shaft running its whole length near the floor level. A novel feature in this machine is that the three sections are driven by chain gearing, and the builders believe this is the first example for a machine of this sort, and they claim that it is much quieter working than the usual arrangement of spur gearing, the rattle of which causes so much annoyance. Another feature is that the central hollow shaft which carries the revolving part of the machine is provided at each end with heads which run on adjustable antifriction rollers, and as the centre discs also run on similar rollers, the machine requires comparatively little power to drive it. We understand that the machine is capable of making about three miles of cable per working day. Amongst other machines recently made by this firm is one for the Postal Telegraph Department for making 7-wire gutta-percha cables interlaid with yarns, the whole covered with compound tape, in one operation.



PAST YEAR'S WORK.—Continuing our reports from leading firms as to the progress of the electrical industries for 1895, we have received from Messrs. DRAKE and GORHAM a report that increased business has necessitated enlarged office accommodation and consequent additional staff, and the showrooms for exhibiting the firms' specialities, fittings, &c., have been extended. The Manchester branch has shown satisfactory progress, which has induced the firm to arrange for another branch at Glasgow to deal with the Scotch business. A long list of country installations includes Crewe Hall, where a complete steam and electric plant for 550 lights has been installed; Windlestone Hall, a similar plant, for 300 lights. Other installations include oil engine and water-power plants. The town-house installations include the town residences of the Marquis of Lansdowne, the Duke of Montrose, Lord Wynford, extensions at Devonshire House, Prof. Kennedy's house, and a long list of the town residences of many well-known public men. Public building lighting has included the Prudential Insurance Company's installation, equivalent to 375 H.P.; the Stafford Technical Schools (1,100 lights), Baliol College (370), Convalescent Home, Little Hampton (230), Stafford County Infirmary (230), Cancer Hospital (320), Lancaster Infirmary (240), St. Paul's Church, Deptford (110), St. Michael's Church, Chester-square (200), the gas stove showrooms of the Manchester Corporation; additional arc and incandescent lighting at the University Galleries, the extensive offices of the Council of Foreign Bondholders, the South-Eastern Railway Company's Offices at Edenbridge, the North-Eastern Railway Company's offices, Messrs. Allsopp and Sons' offices, &c., &c., the whole work showing the extensive range of Messrs. Drake and Gorham's business, and the facilities which the firm's experience offers for installations of almost every variety, whether with steam, gas, oil or water power. Other work carried out during the year has included the organisation and equipment of the Jandus Arc Lamp and Electrical Company, at Charlton, which enables the Company

Digitized by Google

to manufacture and supply all parts of these lamps; the D.P. Battery business has been organised into a separate company; and business in connection with the sale of the earthing devices and other apparatus of the firm has also increased to a gratifying extent, the sale of the earthing devices showing 3,500 of these instruments now in daily use, and the report as to their efficient working is to the effect that "no single case is known to have occurred of the apparatus having failed to effect its purpose."

PAST YEAR'S WORK.—Mr. A. P. LUNDBERG, inventor and manufacturer of several well-known types of switches and other electrical apparatus and fittings, reports that business during 1895 has been satisfactory, and has shown considerable improvement on 1894. The close of the year brings up the total of the "Unique" switch invented by Mr. Lundberg to 90,000, turned out from his own works. Although Continental competition has proved severe, Mr. Lundberg reports that it has been satisfactorily met, and that fair orders have been received from Germany and other countries. Trade with the Colonies, particularly with Australia, South Africa and India, and in addition, with South America, has shown satisfactory increase.

CATALOGUE.—The General Electric Company (Limited) have this year surpassed their former efforts, and have produced a catalogue which, both in the completeness of its information and in the artistic manner in which it has been produced, may be considered perfect. No pains have been spared to make this a useful work of reference, alike for the contractor, the consulting engineer and the consumer of electricity. The book, which comprises nearly 1,000 copiously illustrated pages, includes special sections on almost every branch of electrical industry, and is strongly bound in serviceable stiff cloth covers. An Appendix contains an exhaustive index of all the sections, together with a code for telegraphic purposes, and a large quantity of generally useful information. Among this last-named we notice a glossary of electrical terms and a list of useful electrical books (in which there are, however, numerous misprints). We understand that a nominal charge of 10s. is made for the catalogue, and that this sum is returned upon receipt of the first order directly or indirectly obtained through it.

POCKET PRICE LIST.—We have received from the Chloride Electrical Storage Syndicate (Limited), 16, Victoria-street, S.W., a copy of the fourth edition of their useful pocket "Price List of Chloride Batteries." Battery users will find the pocket-book of assistance. It is strongly bound, and not being too small, the type is clear and readable.

CASSIER'S MAGAZINE.—Amongst the subjects of interest to our readers dealt with in the January issue of this magazine are the following articles:—"Municipal Electric Lighting from Underground Mains," by E. J. Houston and A. E. Kennelly; "Gas Engines for Electric Light and Power," by N. W. Perry; "When is it Advantageous to use Water Power for Electric Transmission?" by C. E. Emery; "The Induction Motor," by Louis Bell; "Electricity for Propelling Railroad Trains at Very High Speeds," by H. S. Maxim; "Electric Pumping Machinery," by C. A. Hague; "Direct Production of Electric Energy," by L. Duncan; "Electrically Operated Factories," by R. E. Crompton; "Electrical Power in Canada," by J. S. Robertson, &c. Many of the writers are leading electrical experts in America, in which country Cassier's Magazine has a well-deserved reputation.

MACHINERY LISTS.—We have received a copy of a new list just issued as a weekly edition of "Machinery Implements and Mill Furnishings Wanted Lists," by Mr. A. Tolhausen, Fountain-street, Manchester.

CALENDARS.—A useful date remembrancer is issued by Messrs. W. H. Willcox and Co., the well-known suppliers of engineers' stores, &c., of Southwark-street, London, S.E. In addition to its usefulness as a calendar, a large number of Messrs. Willcox and Co.'s specialities are illustrated on the sheets, which can be readily referred to when such goods are required.——Mr. J. Vickers, advertising contractor, of Nicholas-lane, E.C., sends a very useful sheet month-by-month calendar, neatly printed in colours, in which the dates stand out very prominently, a point sometimes lost sight of. ——Messrs. King and Co., of the Leith Electric Works, Leith, Scotland, have sent us a neat hanging calendar which shows originality of design.——A useful hanging Sheet Calendar is forwarded by Messrs. Sankey and Son, makers of fire-clay goods, of Canning Town, E., the sheets being illustrated and giving descriptions of boiler-seating blocks, flue covers, stoneware pipes, &c.——A neat and handy calendar pad is sent by an American firm, makers of the "Columbia" bicycles, Hartford, Conn. This is in the form of a desk-note pad, in flexible metal case, with tear-off memoranda sheets.

ALSAGER.—The Urban District Council have decided to light the district electrically. A meeting of ratepayers will shortly be held to discuss the proposal.

AYR.—The electric supply station at Ayr was formally opened on Wednesday evening by Lord Kelvin, who was accompanied by Lady Kelvin. The work has been carried out under the professional supervision of Mr. Robert Hammond and of the resident engineer, Mr. Ernest G. Pink. As our readers are aware the site of the central station is in Mill-street. The building, which cost between £2,000 and £3,000, has been designed to allow of considerable extensions when required. The capital expenditure up to date on buildings, plant, machinery, &c., has been about £20,000. Provost Willock presided at the inaugural ceremony, and gave details of the progress of the work from its initiation. Lord Kelvin, in opening the station, said he thought the work in connection with the station would prove a credit to all concerned. Mr. Hammond subsequently moved a vote of thanks to Lord Kelvin, and pointed to the fact that with the addition of Ayr to the list of municipal electric lighting stations the number of those now supplying current was 47, while the number of electric supply companies was also 47. Only a few of the principal thoroughfares are at present lighted. The price of current has been fixed at 7d.

BANGOR.—At the meeting of the City Council on Wednesday the Electric Lighting Committee recommended that application be made to the Local Government Board for sanction to borrow £15,000 for the purpose of establishing electric lighting works. After discussion, the Committee's proposal was agreed to.

BANGOR (CO. DOWN).—The Township Commissioners have again discussed the electric lighting question, and have now decided to apply for a Provisional Order.

BIRMINGHAM.—At the meeting of the Public Works Committee on Monday last the question of the adoption of the overhead system of electric traction on the Nechells tramway route was further considered, but owing to the absence of a prominent member no definite decision was arrived at. The report of the Committee will not, therefore, be presented to the City Council until the February meeting of that body. A petition in favour of the system, and which has been numerously signed by the inhabitants of the Nechells and adjoining districts, was presented to the Council at its meeting on Tuesday.

BLACKPOOL.—The Town Council have remodelled the discounts allowed to large consumers of electric current.

BRIGHTON.—At the last meeting of the Town Council the chief point of discussion was the lighting of the side streets by electricity. The councillors were almost unanimous in their appreciation of the labours of the Electric Lighting Committee; so much is this the case that it is reasonable to expect that a scramble will ensue for membership of that Committee in the near future. Even Councillor Evans, who struck a discordant note at the meeting, agreed that the electric light was a great improvement upon gas. Councillor Swaffham, in reply to the remarks of members, pointed out that it was the increased brilliancy of the street illumination that made the bad lighting of the side streets by gas so painfully conspicuous.

BRISTOL.—Mr. H. Faraday Proctor (the borough electrical engineer) has presented his amended report on the question of lighting the Mansion House electrically, and, as the members of the Finance Committee were divided as to the advisability of carrying out the work, the matter has now been referred to the Mansion House Committee for consideration and report.——The electric lighting undertaking of the Corporation is evidently progressing in a very steady and satisfactory manner. It is stated that the number of customers has greatly increased since October 1st, and that the works are now being run at an actual profit. At present there are over 24,000 lamps connected, but there are orders in hand for 3,500 more, or a total of 27,500. It is anticipated that additional machinery will shortly be required if the demand continues to increase at the present rate. The Electric Lighting Committee have just decided to reduce the price of current for motor purposes to 4d. per unit, as an earnest of the Committee's efforts to increase the day load.

CHATHAM.—The instructions received from the Admiralty for the preparation of the "Theseus" and "Charybdis" for active service necessitated gangs of workmen being employed at night, and the electric light at the Dockyard proved of great service.

CHELTENHAM.—As usual, the report of the Electric Lighting Committee presented at Monday's meeting of the Town Council was very favourable, and gave evidence of a continually-increasing demand for electric current in this town. During the month 750 additional 8 c.p. lamps were connected, bringing the total to 5,050, while 500 are awaiting connection.

CHURCH LIGHTING.—The United Presbyterian Church, Palmerston-place, Edinburgh, is now lighted electrically. It is claimed that this is the first church in Edinburgh to adopt the electric light. About 170 incandescents, varying from 16 c.p. to 32 c.p., are employed.——The Dereham-road Methodist Chapel, Norwich, is now lighted electrically. The work has been carried out by Messrs. Woolnough, Proctor and Co.

CLACTON.—A member of the District Council has given notice of his intention to move at the next meeting of the Council that tenders be invited for the electric lighting of the town.

Digitized by Google

DERBY AND ASHBOURNE ELECTRIC TRAMWAY.—In the Bill which the promoters of this undertaking propose to introduce in the next Session of Parliament power is sought for the incorporation of a Company, with a capital of £87,500. The first directors are: Sir H. Wilmot, Bart., Hon. F. Strutt, Mr. A. C. Duncombe, and Messrs. G. T. Meynell and J. Shaw. Power is also sought to enable the Company to pay interest out of capital during the construction of the tramway to an extent not exceeding £10,000.

ECCLES.—At a special meeting of the Town Council on Monday last, the electric lighting question occupied the attention of the councillors for several hours. In October last the tender of the Manchester Edison Swan Company for the supply of the necessary plant for the proposed electricity works was recommended for acceptance, but, owing to the proximity of the November municipal elections, no decision was then arrived at. Recently the Council authorised the Electric Lighting Committee "to take measures to inform the ratepayers of the details of the plan which had been considered by the Committee," and the Committee subsequently decided to distribute several thousand explanatory pamphlets to the ratepayers. Mr. Mellor proposed that a public meeting should be called for the purpose of deciding on some course of action, but this motion was defeated by the casting vote of the Mayor.

EDINBURGH.—At the meeting of the Town Council on Tuesday, Councillor Mackenzie, in moving the adoption of the Electric Lighting Committee's report, referred to in our last issue, said the members of the Committee were desirous of leaving the entire responsibility of deciding whether the streets mentioned in the report should be lighted electrically or not with the Council, but he made a detailed statement of the expenditure which the suggested extensions would involve, and of the cost of maintenance, &c. Mr. E. W. Monkhouse's recent report shows that up to December 26th the number of units of current sold was equal in value to between £1,400 and £1,500 more than the Electric Lighting Committee had anticipated. Up to the present it is estimated that a capital expenditure of £12,500 has been incurred for the public lighting. The current (480,000 units) for the 250 public lamps has been calculated to have cost the Corporation 1¼d. per unit, and has shown a small profit at this low figure. Ultimately the subject of the proposed extensions was remitted to the Cleaning and Lighting Committee for report.

ELECTRIC TRACTION IN RUSSIA.—It is reported that the construction of a system of electric tramways in Riga is in contemplation.

EXETER.—Col. J. Ord Hasted, R.E., held a Local Government Board inquiry yesterday (Thursday) into the application of the City Council for leave to borrow £11,000 for the purchase of the plant and undertaking of the Exeter Electric Light Company.

FAREHAM.—At the ordinary meeting of the District Council on Tuesday electric lighting matters occupied considerable attention. A resolution was proposed by the Chairman in the terms of which the solicitors to the Council were instructed to accept the offer of the Fareham Electric Light Company to carry out the contract of August 16, 1894, by which the purchase of the Company's undertaking by the Council was agreed upon in lieu of paying the damages awarded in the recent action, and, further, to apply for a stay of execution of that order to enable the Council to complete the purchase. This resolution was carried. A proposal that the application now before the Local Government Board granting powers to the Council to borrow £7,000 for the purchase of the electric light works, &c., be abandoned was not seconded. The vanquished at Fareham do not appear to take their defeat at all kindly, but the resolution of the Council clears the way for an amicable understanding.

HAMPSTEAD (LONDON).—Further extensions of the electric light mains to Redington-road, Goldhurst-terrace, and Canfield-gardens, have been sanctioned.

ISLINGTON (LONDON).—The Lord Mayor has fixed Wednesday, March 4th, for the formal opening of the electricity works at Eden-grove.

KIMBLESWORTH AND PLAWSWORTH (DURHAM).—The ratepayers of these townships in September last adopted the Lighting Act and decided to light the villages by electricity. The Kimblesworth Colliery Company having been approached on the subject of supplying the necessary current, satisfactory arrangements have been made, the Colliery Company providing the generating plant and the two Councils the mains, lamps, &c. The Corlett Electrical Engineering Company secured the contract for the work, which has now been completed, and is giving every satisfaction.

KING'S NORTON.—At Wednesday's meeting of the Rural District Council a letter was received from the Birmingham and Central Tramways Company, asking for sanction to continue running their cars through the Council's district, on a portion of the Bristol-road route, for the ensuing year, and pointing out that under present conditions the Company were restricted to one kind of motor. There were now several improved kinds of motors on the market, and the Council were asked to cancel the restriction. Mr. T. A. Bayliss said that the Company evidently intended to introduce the overhead electric system upon the Bristol-road route, and, if that was so, he should strongly oppose it. The Council decided to grant the licence to the Company, and to allow them to alter their motors in any way they thought fit, so long as they did not adopt the overhead system.

KINGSWOOD (BRISTOL).—At the meeting of the District Council, on Wednesday, a resolution was passed legalising the recent extension of the elcctric tramways from the King's Arms to Warmley Hill.

"KNOWLEDGE."—With the number for January, *Knowledge* commences a new volume. A coloured supplement plate is issued of the planet Jupiter.

LEICESTER.—The Waterworks Committee have decided to adopt Mr. George Jennings' system of electro-mechanical apparatus for indicating and registering between the new reservoirs and engine houses at Swithland, Hallgates and Cropstone, the varying levels of water in the reservoirs.

LINCOLN.—At the last meeting of the Town Council a joint report from the Lighting, Building and Improvement Committee and the Gasworks Committee, was presented and discussed. The report recommended the Council to oppose the application of the County of London and Brush Provincial Company for a Provisional Order, and that a Special Committee be appointed to consider and report upon the advisability of adopting an electric lighting scheme for the town. Alderman Page, in moving the adoption of the report, said the members of the Committee were unanimously in favour of electric lighting being in the hands of the Council.

LLANELLY.—At the meeting of the Town Council on Monday last a letter was received from Mr. J. C. Howell, asking if the Council would be prepared to entertain an offer from his firm for the electric lighting of the Market, the New Town Hall, and the Athenæum, and for erecting about 20 arc lamps in Vaughan, Stepney, Powell, Murray and Salamanca-streets, and the New Town Hall-square to Bridge and Market-streets; and, if so, to state the maximum price they would be prepared to pay for a ten-years' contract. The letter was referred to the Estate Committee for consideration and report.

MANSION LIGHTING.—The contract for the electric lighting of the Duke of Fife's new mansion on Deeside has been given to Messrs. P. C. Middleton and Co., of Aberdeen.

MERTHYR TYDFIL.—The District Council have referred the question of opposing the application of Messrs. J. C. Howell (Limited) for a Provisional Electric Lighting Order to a committee for consideration and report.

NEWCASTLE-ON-TYNE.—At the meeting of the Town Council, on Wednesday, the letters received from the British Thomson-Houston (Limited) and the British Electric Traction (Pioneer) Company, offering to electrically equip the Newcastle tramways on terms referred to in our last issue, evoked a long discussion. On the suggestion of Alderman Sir Charles Hamond, M.P., the letters were referred to the Town Improvements Committee for consideration and report. At a public meeting in the Hunters'-road Board School, on the same evening, a resolution protesting against the Council's tramway scheme was passed.——The Quayside Committee of the Corporation intend to make a survey of the Quayside on Monday next, for the purpose of ascertaining what increased shipping accommodation and other facilities can be provided, and also to see whether it is advisable to instal the electric light, and thus enable shippers to load and unload their vessels with greater despatch and convenience than they do at present with the very primitive torch lights.

NEWCASTLE-UNDER-LYME.—The General Purposes Committee reported at the meeting of the Town Council on Tuesday last that they had a final interview that afternoon with Messrs. Sellon, Carruthers Wain, and Milward (representing the North Staffordshire Tramways Company), when it was recommended that a communication be sent to the Board of Trade objecting to the granting of the Provisional Order to extend the tramway to Newcastle. The minutes were agreed to.

NEWPORT (SALOP).—The District Council intend to appoint a committee for the purpose of considering the question of lighting the district electrically.

NIAGARA FALLS.—Power, street railway and electrical circles generally in the Dominion of Canada are fully aroused by a legal notice appearing in the Canadian papers stating that application will be made at the next session of Parliament for an act to incorporate "The Canadian Electric Railway and Power Company with power to build, operate and maintain an electric railway from the City of Montreal in the Province of Quebec to the city of Windsor in the county of Essex *vid* Brockville, Kingston, Belleville, Toronto and London, with power to build a branch line to Suspension Bridge (Niagara Falls), with power to build branch lines for a radius not exceeding 25 miles from any point or points on the main lines; to

Digitized by Google

enter into contract and arrangements with all existing or authorised firms or corporations along the said route, and particularly with existing street or electric railway, light or power companies for the purpose of acquiring, leasing, amalgamating or making running arrangements with same, or to supply same with heat, light or power; to establish, maintain and carry on street railway services in such cities and towns on the line of said railway as the Company and municipalities interested may agree on; to build said railway in sections as may be authorised; to acquire water powers and sites for and build electric works in connection with said railway for the purpose of generating electrical energy, to acquire the right of way to transmit and also the right to sell and otherwise dispose of electrical energy for heat, light, power and other purposes and to distribute the same; with power to expropriate lands for the purposes of the undertaking as provided by the Railway Act; with all other powers necessary for constructing and operating the said electrical works, and to otherwise fully carry on the said undertaking, with power to issue paid-up stock of the Company in payment of its obligations for all or any of the said authorised purposes, and with all proper or usual powers given or granted to companies incorporated for any of the purposes aforesaid."

PATENTS.—The total number of patents applied for for 1895 was 25,116, against 25,386 and 25,067 in 1894 and 1893.

STAINES (MIDDLESEX).—Messrs. Reffel and Co. have introduced the electric light into their extensive range of stables and cow-sheds, and the two farms belonging to the Company are now connected by telephone.

SWANSEA.—The Corporation intends to promote a Bill in Parliament to confirm an agreement with the Swansea Improvements and Tramway Company for the sale of the Company's tramways to the Corporation, and for the granting of a lease to the Company for 21 years of the same, together with any additional lines that may be constructed by the Corporation. Power to borrow £149,000 in connection with this scheme is also sought.——At a public meeting convened by the Mayor and the residents of the four central wards of the borough, the triple scheme of electric light, tramways and dust destructor, was discussed. The Mayor pointed out that the Corporation had an opportunity of acquiring the tramways on favourable terms, and it was the general opinion that the lighting of the town should be in the hands of the governing authority. The time had come when they must decide either to supply electric current themselves or hand its supply over to a Company. With regard to the dust destructor portion of the scheme, their engineer was of opinion that the erection of a dust destructor would save them £400 a year, and relieve them of the difficulty of dust disposal. Mr. Manville, who was present, and whose scheme was under discussion, went fully into the merits of the combined undertaking, and especially pointed to the district of Swansea as one in which special sources of profit would be available, enabling the price charged for current to be abnormally low. The meeting, on the whole, was favourable to the scheme.

WALLASEY.—The engineer recently submitted to the District Council the details of an electric lighting scheme, which was estimated to entail an initial expenditure of about £12,500. The engineer recommended the Council to adopt the high-tension alternating-current system of distribution, and to erect the generating station on the site of the Liscard pumping station, while transformer sub-stations would be built at New Brighton, Egremont, Seacombe, Liscard, and Wallasey. The Council have decided to carry out the engineer's scheme.

WESTMINSTER (LONDON).—As a result of a report by the Surveyor on the advisability of establishing joint refuse destructor and electric lighting works, the Joint Works and Sanitary Committee have decided to appoint a sub-committee to obtain further information.

WESTRALIAN TELEGRAPHS.—The telegraph line is now completed as far as Menzies, placing that town in telegraphic communication with Coolgardie and other important mining districts. The first message was sent over the wires on December 3rd.

WIGAN.—At the last meeting of the Town Council Alderman Holmes, in moving the adoption of the Gas and Electric Lighting Committee's report, stated that considerable progress had been made with the arrangements for lighting the borough electrically; tenders for the buildings had been invited, and every effort would be made to have a supply of current available for the next winter.]

WILMSLOW (CHESHIRE).—At the last meeting of the District Council the subject of the establishment of electric light works was considered, and, after a lengthy debate, it was decided to adjourn the matter for 12 months.

WITTON GILBERT (DURHAM).—The principal thoroughfares of this township are now lighted by electricity, the inaugural ceremony taking place last week. The work has been carried out by the Corlett Electrical Engineering Company. The incandescent lighting has been adopted, a Crompton dynamo supplying current to about 180 16 c.p. lamps. The farthest light is two miles from the machine. The installation has created considerable interest in the neighbourhood, many of the surrounding districts being represented at the opening ceremony.

WORCESTER.—An action has been commenced against the Corporation by Messrs. T. C. and W. H. Quarrell and T. White claiming damages and an injunction in connection with Powick Weir, the waters of which are used in the Corporation's electricity scheme.

YEADON.—The District Council recently decided to canvass the principal ratepayers in order to ascertain the amount of support likely to be given to their suggested electric lighting scheme. Of the 263 voting papers which have been returned, 154 were blank, 33 favourable to the establishment of electricity works, and 76 against. At their last meeting, the Council decided not to hold the adjourned ratepayers' meeting, which had been fixed to discuss the subject, and to drop the scheme altogether.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

November 27, 1895.

22,660. W. THOMSON (Baron Kelvin). Glasgow. Apparatus to protect against danger from overhead electric wires.

22,661. W. THOMSON (Baron Kelvin). Glasgow. Improvements in apparatus for indicating and recording electric supply.

22,679. G. WADELY. London. Improvements in the construction of electric light fittings.

22,686. C. D. ABEL. London. Improved automatic electromagnetic interrupter for protecting electrical installations. (Compagnie pour la Fabrication des Compteurs et Materiel d'Usines à Gaz, France.)

22,696. W. P. THOMPSON. Liverpool. Improvements in alternating-current arc lamps. (W. Mathiesen, Germany.)*

22,717. M. KOTYRA and C. MILDÉ. London. Improvements in telephonic apparatus.

November 28, 1895.

22,783. J. D. GREENE and B. WARNE-BROWNE. London. An improved attachment for telephone receivers.

22,793. W. ROWBOTHAM. Birmingham. Improvements in and relating to electric vapour engines for vehicle and launch propulsion in particular.

November 29, 1895.

22,846. F. G. ROBINSON. Liverpool. Improvements in and connected with automatically operated electrical switches.

22,864. A. PIEDFORT. London. Improvements in and relating to telegraphic receivers, especially applicable for submarine telegraphy.

22,866. A. F. B. GOMESS. London. Improvements in the extraction of copper from its ores by electrolysis.

22,898. R. T. GROCOTT. London. Improvements in the manufacture of electrical fuseboards and other like articles.

22,899. J. E. BOUSFIELD (of the firm of G. F. Redfern and Co). London. Improvements in and connected with secondary batteries. (G. Dorville and Co., France.)

November 30, 1895.

22,936. T. F. J. TRUSS. Liverpool. Improvements in and connected with electrical commutators and collector rings, and collectors therefor.

22,939. F. G. GRIFFITH. London. Improvements in electrical sounding apparatus.

22,976. J. SWINBURNE. London. Improvements connected with electric telegraphs, organs, condensers, deposition of nickel and cobalt, and with packing eggs and other fragile articles, and coating eyelets and such objects, and making bleaching powder.

22,985. C. BREMER. London. A contact device for the transmission of electric current.*

22,987. M. M. HARRIS and G. CUTHBERT. London. An improved electrical lamp and battery, especially applicable for use in bedrooms, but applicable for various other purposes.

December 2, 1895.

23,002. F. H. PERRY. Birmingham. Improvements in electrical batteries.

December 3, 1895.

23,083. E. HODGSON, J. WALKER and A. BLACKBURN. Cleckheaton. An improved armature for dynamo-electric machines.

23,097. R. HEATHFIELD and W. S. RAWSON. London. Improvements connected with the electrical deposition of zinc.

23,109. W. M. CLOSE. Cobham. Improved electric switch for key, socket, main, or ordinary switches.

23,111. H. F. JOEL and F. FANTA. London. Improvements in electric incandescent lamps.

23,165. A. C. Miles and B. F. de Morgenstern. London. Improvements in and relating to galvanic batteries.

December 4, 1895.

23,174. J. Hewett. London. Improvements in electric arc lamps.

23,189. H. A. Schlesinger (as agent for L. Sandoz, Geneva). New pantelegraph for transmitting in fac-simile autographic telegraphic messages in handwriting, print, sketch, design, &c.

23,250. F. W. Schneider. London. Improved paste carrying plates for electric accumulators.*

December 5, 1895.

23,259. S. Rowbottom and J. Roe. Manchester. An improved reflector for incandescent electric light globes or bulbs.

23,332. W. J. Davy. London. An improved rheostat.

23,338. H. J. Fisher. London. Improvements in or relating to electric arc lamps.

23,354. F. Le Roy. Liverpool. Improvements in electric heating devices.*

December 6, 1895.

23,404. F. Zapata. London. Improvements in electric motors.

23,415. M. Freudenberg. London. Improvements in or relating to electric arc lamps.

23,426. R. Belfield. London. Improvements in electric signalling.

23,427. A. W. Cramer and B. I. Milligan. Manchester. Improvements in the manufacture of material suitable for insulating purposes.

December 7, 1895.

23,459. E. Andreoli. London. Electro-depositing on and stripping gold from cathodes.

23,462. H. G. Cotsworth. Swindon. Improvements in the striking and regulating mechanism of arc lamps.

23,496. R. Belfield. London. Improvements relating to electric railways.

23,515. A. F. Borel. London. Improvements in the manufacture of electric cables.

23,519. A. J. P. Whitaker and F. G. Treharne. London. Improvements in electrical insulators and insulating compositions.

December 9th, 1895.

23,564. Alexander Schanschieff. London. Improvements in alloys applicable for solders, electrical safety plugs, fire alarms, heat indicators, and the like.

December 10th, 1895.

23,658. A. Rosenholz and H. E. Poehlman. London. Switches for underground electric railways.

23,670. P. H. Guerin. London. Improvements in methods of lighting by electric arc lamps.

December 12th, 1895.

23,811. W. de Graaff. Liverpool. Improvements in or connected with dynamo-electric generators.

23,841. H. G. Brain. London. An electrical system and apparatus for synchronously indicating at one or more distant points the distance registered by a ship's log.

23,844. E. Shore. Liverpool. Improvements in mooring swivels or apparatus for use in connection with lightships, guardships, or other floating bodies that are connected with the shore by electric or telegraphic cables.

23,855. The Edison and Swan United Electric Light Company (Limited) and C. F. Proctor. London. Improvements in electrical switches.

23,857. R. J. Crowley. London. New or improved system of telegraphy and telephony.

23,865. A. J. Boult. London. Improvements in or relating to thermo-electric generators. (A. Wimderlich, Belgium.)

December 13th, 1895.

23,892. W. J. McCaw. Glasgow. Improved means for conveying currents to electric motor cars, or streets, or roadways.

23,894. C. L. Clarke and W. P. Theerman. Manchester. Improvements in telephones and telephone switches or line selectors.

23,922. Siemens Bros. and Co. (Limited). London. Improved means for compensating variations of load at electrical stations. (Messrs. Siemens and Halske, Germany.)

23,943. R. C. Quin and H. Reason. London. Improvements in the lighting of streets and the like by incandescent electric lamps.

23,952. H. Fewson. London. Improvements in and relating to electric batteries.

December 14th, 1895.

23,976. J. J. P. Barker and J. S. Blackwell. Leicester. Improvements in ball-joint fittings to be used for electric lighting.

23,994. A. G. Adams. Bedford. Dynamo machines for producing alternating electric currents of low tension.

24,020. Siemens Bros. and Co. (Limited). London. Improvements in safety-fuse devices for electrical installations. (Siemens and Halske, Germany.)

24,021. Siemens Bros. and Co. (Limited). Improvements in switches for connecting two or more electromotors.

24,037. L. H. Watters. London. Electric programme or bell ringing clock.

December 16, 1895.

24,049. A. J. Moulart and Adrien de Galard. Brussels. Improvements in electrical contacts.

24,055. R. C. Quin. Brighton. Improvements in the construction of electric cable joint boxes, more especially for those of concentric type.

24,079. W. E. Parry. London. Improvements in collectors for electric railways and tramways. (J. Parry, United States.)

24,092. C. Vreede. London. Contact apparatus for night and sound signalling and telegraphing.

24,098. A. de Puydt and M. Poncin. London. Improvements in continuous-current generator dynamos or motor dynamos.*

December 17, 1895.

24,136. H. Brecknell and Thomas B. Holliday. Bristol. An automatic check or governor for controlling the trolley (trolley-wire system of electric traction).

24,165. L. Epstein. London. Process for hardening the active material on the positive plates of secondary voltaic batteries.

24,166. The Edison and Swan United Electric Light Company (Limited) and E. A. Gimingham. London. Improvements in incandescent electric lamps.*

24,172. A. C. Iwanowski. Liverpool. Improvements in or connected with galvanic batteries.

December 18, 1895.

24,222. D. Sinclair. Glasgow. Improvements in multiplex telephony.

24,264. Siemens Bros. and Co. (Limited). London. Resistance switch apparatus for starting electro-motors. (Siemens and Halske, Germany.)

24,296. A. B. Blackburn and W. L. Spence. London. Improvements in or connected with rotary electric transformers.

24,304. M. Bailey and J. Warner. London. Improvements in incandescent electric lamps.

December 19, 1895.

6,565A. H. Tee. Liverpool. Improvements connected with the electrolysis of chlorides and other salts and the evaporation of solutions. (Date claimed under Patents, Rule 19, March 30, 1895.)

24,354. C. M. Dorman, R. A. Smith and H. G. Baggs. Manchester. Improvements in electrical switches.*

24,375. J. H. Hegner. Liverpool. Improvements in electric arc lamps.*

24,394. Audley C. Miles and B. F. de Morgenstern. London. Improvements in and relating to galvanic batteries.

24,398. C. Pollak. London. Improvements in means for controlling or directing electric currents.

December 20, 1895.

24,437. The Anglo-Swedish Trading Association (Limited) and O. E. Wollert. London. Improvements in electrical and other gas-lighters and extinguishers.*

24,443. S. F. Walker. Cardiff. Improvements in portable electric lamps for use in mines and other places.

24,444. E. Hungerbühler and The Electrical Company (Limited). London. Improvements in holders for electric lamps for use in mines and other places.

24,465. A. C. Miles and B. F. de Morgenstern. London. An improved electric contact button.

24,466. A. C. Miles and B. F. de Morgenstern. London. Improvements in electric indicators.

24,467. A. C. Miles and B. F. de Morgenstern. London. Improvements in incandescent lamps.

24,471. V. A. Fynn and Easton, Anderson and Goolden (Limited). London. Improvements in devices for protecting electric circuits and apparatus from injury by excessive electrical potential due to lightning or other causes.

24,472. V. A. Fynn and Easton, Anderson and Goolden (Limited). London. Improvements in dynamo-electric machinery.

24,473. C. H. Stearn. London. Improvements in or connected with incandescence lamps and filaments therefor. (C. F. Topham, Switzerland.)

December 21, 1895.

24,503. R. Atherton. London. Improved electric insulators.

24,514. R. Hacking and J. Bennett. London. Improved means or devices for holding electric incandescent or glow lamps.*

24,516. Ludwig Epstein. London. Improvements in secondary voltaic batteries.*

24,539. A. C. Miles and B. F. de Morgenstern. London. Improvements in electric regulators.

24,556. E. Jullien. London. Improvements in suspension devices for electric and other lamps.

December 23, 1895.

24,577. T. Laurie. Falkirk. Improvements in movable supports for movable flexible electric conductors.

24,578. D. Urquhart and F. Wynne. London. Improvements in the application of electricity to vehicles on tram and railways, and in the apparatus for effecting the same.

COMPANIES' MEETINGS AND REPORTS.

Fowler-Waring Cables Company (Limited).

The report of the Directors of this Company, which was presented at the sixth ordinary general meeting of the Company, held on the 30th ult., calls attention to the negotiations which were proceeded with during the year with the object of bringing about a reconstruction of the Company, which would have secured to the shareholders a valuable interest in the new Company at that time projected. These negotiations, however, fell through, and at the meeting further proposals were presented. The report continues:—"It has long been clear that it is essential to add to our productions other classes of electrical cables than the special lead-covered type for the manufacture of which the Company was originally formed. Applications to the shareholders for capital to aid thed evelopment of their business have been found to be useless, and the Directors have themselves found the necessary funds for its continuation. The time, however, has now come when a decision must be taken between two alternatives, liquidation, or the introduction of new capital to allow of the extension of the Company's operations to other branches of the industry, in which, for lack of capital, it has hitherto been unable to compete." The Directors at the meeting recommended the latter course, and a scheme for reconstruction, setting forth their financial proposals, was submitted. The report further stated that the losses on trading were very heavy during 1894, in consequence of heavy fixed charges, which could not be materially reduced so long as the Company was kept in a position to execute the large orders which might then have been expected, and which, to some extent, have come to us. These orders were not sufficiently numerous, and the competition was severe for those which were obtained. The loss on trading was not so heavy during 1895, but until a few months ago it has been continued, and, were it not for the fact that recently much larger contracts have been secured, and that there have passed into the hands of the Company several important improvements relating to cable manufacture, the Directors would not feel themselves at all justified in recommending the continuance of the business. In the many important contracts carried out by the Company its work had been uniformly successful; but changes in electrical business are continually occurring, and it has become evident that, however important in itself, the manufacture of lead-covered cables alone cannot ensure success. Having, therefore, secured for the Company a high reputation for the manufacture of this class of cable, the Directors proposed to save the business by increasing its scope and extending its operations. In connection with the improvements referred to above, the Directors state that they have obtained an advantageous option for the purchase of a patent for the production of a substitute for india-rubber and gutta-percha. This material has been thoroughly tested at the works, and the Directors are satisfied that it possesses properties of a real commercial value in various directions, and especially in the manufacture of electrical wires and cables, and that this development should render possible a great extension of the business. To wind up the Company at once and realise its assets might, the report continues, appear the simplest and least troublesome course; but under a break-up it is scarcely possible that the shareholders would receive any return of capital, as it must involve the loss of a connection and experience which have cost much, as well as the forced sale of assets

Digitized by Google

which are of great value to a going concern. The Directors therefore recommend reconstruction.

At the meeting we learn the Directors' proposals were agreed to, the retiring Directors and auditors re-elected, and the resolutions approving the reconstruction of the Company, and appointing Mr. B. J. Diplock (the Secretary) as liquidator in the voluntary winding-up of the old Company, were passed, to be finally approved at a subsequent meeting.

The scheme for reconstruction of the Company provides for a new Company being formed, bearing the same name as the existing Company, with a capital of £200,000, divided into 40,000 shares of £5 each, Ordinary or Preferred. The present Company to be wound up voluntarily, and its property and assets, subject to its liabilities, to be transferred to the new Company in exchange for 4,060 fully paid-up shares of the new Company. As the issued capital of the existing Company is £101,500, or 20,300 shares, this will give to each shareholder of the existing Company one fully paid-up share of the new Company in exchange for each five shares of the present Company, whether Ordinary or Founders' shares. Holders of Mortgage Debentures and prior lien charges of the existing Company, aggregating £28,850, to release their charge upon the property and assets of the Company, and receive in exchange debentures of the new Company to the same amounts at 5 per cent. per annum, and forming part of an issue of £30,000 of debentures, ranking *pari passu* as a first charge upon the undertaking and all property of the Company, subject only to a prior mortgage or mortgages to be created upon the lands and buildings of the Company, to an amount not exceeding £21,000. To provide additional working capital, 4,000 shares of the new Company will be forthwith offered for subscription at par, entitled to a cumulative preferential dividend of not less than 6 per cent., and thereafter to participate rateably with the Ordinary shares in any further division of profits, or on such other terms as the Directors may hereafter determine. The new Company will take over the business and assets as from September 30th last, the trading since that date to be considered as having been carried on on behalf of the new Company. The new Company is to complete all contracts, to pay all debts, and to discharge all liabilities of the existing Company. The expenses of the liquidation of the old Company and the reconstruction of the new Company to be paid by the latter.

The officials of the new Company are the same as those who have for many years managed the old Company, which was established on August 13, 1889.

NEW COMPANIES, STATUTORY RETURNS, &c.

LANGHANS-BERRENBERG-CHAPLIN PATENTS (LIMITED).—This Company was registered on December 31st with a capital of £175,000, in £1 shares, to carry into effect an agreement made between Albert Myers Gibson and the Company, to carry on the business of manufacturers of incandescent and other electric lamps, and of all filaments, wires, bulbs, and other parts and requisites of such lamps; to manufacture pumps, plant and other appliances necessary in the manufacture of incandescent electric lamps; to carry on the business of an electric light company in all its branches, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat and motive power, and manufacturers of and dealers in all apparatus required in connection with the generation, accumulation, supply, utilisation and distribution of electricity. The subscribers are: H. L. Pilkington, P. J. Miller, Templer L. Down, W. A. Smithe, David S. Porteous, A. da Costa and William Wallace.

AFRICAN TRANSCONTINENTAL TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, to December 28th, shows that the whole capital of £140,000, in £1 shares. has been subscribed, and the full amount has been called on 1,306 shares, while a call of 10s. per share has been made on the remaining 138,694, resulting in the receipt of £53,201, leaving £17,537 in arrears.

ARC ACCUMULATOR COMPANY (LIMITED).—This Company's annual return to December 6th, shows that the whole nominal capital of £1,000, in £1 shares, has been taken up, and 993 issued as fully paid. The full amount has been called on the remaining 7, but without result.

ATLAS CARBON MANUFACTURING COMPANY (LIMITED).—The annual return of this Company, to December 2nd, just filed, shows the whole nominal capital of £2,000, in £1 shares, has been taken up, and 1,992 of these have been issued as fully paid, while no calls have been made on the remainder. A resolution for the change of the name to "The Atlas Carbon and Battery Company (Limited)" was passed on November 25th, and confirmed on December 11th.

AUTOMATIC ELECTRIC SIGN COMPANY (LIMITED).—The statutory return of this Company, to December 3rd, has just been filed. The Company has a capital of £5,000, in £1 shares, of which 158 have been subscribed. The full amount per share has been called, resulting in the payment of £108. 15s., leaving £49. 5s. outstanding.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of this Company to October 7th has just been filed. Out of a nominal capital of £750,000, divided into 150,000 Ordinary shares of £3 each, and 150,000 Preference shares of £2 each, 90,000 of each class have been taken up, the full amount called, and £450,000 paid.

CALIFORNIA GAS, WATER AND ELECTRIC LIGHT SYNDICATE (LIMITED).—It is notified that this Company has left its registered office, and repeated requests have been made for the filing of the returns, but without result. Unless this information is forthcoming, the name of the concern will be struck off the register.

CARBON BATTERY COMPANY (LIMITED).—This Company has failed to comply with the regulations of the Companies Acts, and will be formally dissolved unless the returns are forthcoming.

CHELMSFORD ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to December 21st has been filed. The capital is £10,000, divided into 7,500 Preference and 2,500 Ordinary shares of £1 each. The whole of the former and 2,378 of the latter class have been taken up, and the full amount has been called and paid.

ELECTRO-CHEMICAL COMPANY (LIMITED).—The annual return of this Company, to November 19th, has been filed. The capital is £200,000, in 26,000 Preference and 14,000 Ordinary shares of £10 each. 17,710 of the former and all the latter have been taken up, and 5,000 Preference and the Ordinary have been issued as fully paid. The full amount has been called on 12,710 Preference, and £50,699 has been paid.

TOWN AND VILLAGE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, to November 7th, has been filed. The capital is £100,000, in 19,800 Ordinary shares of £5 each and 1,000 Founders' shares of £1 each. Seven of the former class have been subscribed for, but nothing has as yet been called or paid.

VAL D'AOSTA ELECTRIC POWER COMPANY (LIMITED).—The statutory return of this Company to November 13th shows that 250 shares have been subscribed for and allotted, out of a capital of £80,000, in £10 shares, and a call of £5 per share has been made and £1,250 received.

CITY NOTES.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNA OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 922. [Vol. XXXVI. No. 12.] FRIDAY, JANUARY 17, 1896. PRICE SIXPENCE.

NOTES.

TO-DAY we re-publish the steel-plate portrait of Dr. JOHN HOPKINSON engraved on the occasion of his election to the Presidency of the Institution of Electrical Engineers in 1890, and we are glad to think that the hand of time has dealt so gently with Dr. HOPKINSON that the portrait of the President of 1890 is the "counterfeit presentment" of the President of 1896. Much has been said of late about the high-standing in the electrical profession and the many qualifications which ought to distinguish a President of the Institution of Electrical Engineers. In Dr. HOPKINSON we have a Senior Wrangler, a Smith's prizeman, the founder of the scientific method of dynamo designing, and one whose magnetic investigations rightly earned for him a Royal Medal; his recent beautiful research on the rate of propagation of magnetism in iron cores will be within the recollection of all who were able to attend the memorable meeting in the rooms of the Society of Arts last February. The new President of the Institution of Electrical Engineers is peculiarly representative of electrical engineering, which probably contains within its ranks a greater proportion of men in whom science and practice are harmoniously blended than any other branch of "the art of directing the great forces of Nature for the use and convenience of man."

THE central-station engineer sighed in his youth for the electrical analogue of the gasometer. Then he yearned for a day-load, which came not, notwithstanding motors and cooking, and basement-lighting. The great problem has, however, at last received a solution. One need only use parish refuse for fuel, store the heat *à la mode de* Halpin, and negotiate with an obliging tunnel-electric-railway to take a few hundred thousand units per annum, at a fixed price during the hours of light load only. With these three aids to economy, the Shoreditch Vestry seems to be approaching the discovery of the Philosopher's Stone or of Perpetual Motion. This fortunate local authority, as will be seen in another column, has just closed a contract to supply the *in futuro* London, Walthamstow and Epping Forest Railway Company with a minimum of 800,000 units, at 1½d. per unit; the current to be used for tunnel and station lighting, with storage batteries for the evening supply.

THE Railway Company expects to use about 420,000 units a-year. Now, 420,000 units at 1½d. means, as the Electric Lighting Committee point out, £2,625 per annum, and as the engineers are reported to have estimated "that the extra expenses of running the machinery for this quantity of electricity would only amount to about £50 per annum," it is needless to add that the contract was straightway accepted. The offer of the Railway Company is undoubtedly a most advantageous one both to itself and to the Vestry, and we can only hope many more such offers will be made to other metropolitan and provincial electric supply concerns. At the same time it would seem that there must be a cipher missing in that estimate of extra cost. Up to now ·7d. per unit for fuel, leaving oil, waste, water and wages out of consideration, has been considered a good minimum figure without the aid of day-load, dust-fuel and thermal-storage. Can it be that these are going to reduce this figure to less than 0·03d? Perhaps if we multiplied that £50 by 10, we might be somewhat near the *total* extra cost of those 420,000 units.

THE technical gas journals are doing their best to make out that the growth of municipal electric lighting enterprise is a sign of electrical decadence. Doubtless the wish is father to the thought. According to their way of regarding the matter, it is the electrical engineers who, failing to gain the confidence of the capitalist, are attempting to foist a decaying industry upon the hands of sleepy and ignorant municipal corporations. The capitalist, having been bitten and grown twice shy, is, they say, no longer keen upon investing in electricity supply works while any fool can fool a vestry. And our gas friends back up their opinions by pointing out that, in the past, municipal control has been the haven of refuge for more than one shipwrecked commercial venture, *e.g.*, making illuminating gas from sewage or from dustbin refuse. But facts are against our gaseous contemporaries. Many, if not most, of the existing municipal electric lighting schemes have been carried out under Provisional Orders snatched from eager capitalists who would have been glad to have undertaken the work. Take the latest example, at Lincoln, where the application of the County of London and Brush Provincial Electric Lighting Company for a Provisional Order has been refused because the City Council themselves are considering the advisability of providing a supply. Moreover, the gas people should not forget that it is not electric lighting alone that is so "decadent" as to come under municipal control. This tendency towards municipalisation may indeed contain the germs of commercial decadence or of that long overdue New Era; but the eagerness of the Local Authorities to do their own electric lighting, far from

Digitized by Google

denoting the decadence of the electrical industry itself, is an outward and visible sign of a well-founded belief in its vigour and profitableness. Even a Vestry may be trusted not to indulge in an obviously losing business.

Of the various methods of reducing the light from an incandescent lamp, and they are many, perhaps the most ingenious is that which has been invented by Mr. Macfarlane Moore, and which was described by him in a Paper which he read before the American Institute of Electrical Engineers in 1893. Recently-published tests of this method show it to possess, at any rate, a higher efficiency than can be claimed for any other contrivance intended for the same purpose, not excepting the choking coil or the opposition of storage cells. Mr. Moore's method, which sounds "terribly scientific," consists in placing in circuit with the lamp, the light of which is to be controlled, a regulator composed of a make-and-break contact rapidly working in a vacuum. The whole apparatus, excepting the magnet, may be placed in a tube not more than an inch in length, and of the diameter of an ordinary lead pencil. Tests have been made of this apparatus in circuit with a 17 c.p. lamp, and have been compared with the results obtained when an ordinary rheostat replaced the interruptor. The difference, as might be expected, is more marked in proportion to the amount of dimming of the lamp. Thus, when the light was reduced to 10 c.p. there was no observed difference between the current in the two cases; but when it was reduced to 4 c.p. a current of only 0·38 ampere sufficed with the vibrator in circuit, while 0·45 ampere passed when the control was by means of the rheostat; and at 1·1 c.p. the currents were 0·26 and 0·36 ampere respectively. Notwithstanding the sound-deadening effect of the vacuum, we should not like to recommend Mr. Macfarlane Moore's device to a light sleeper. It is true that an old stocking would probably effectually quench the hubbub of the night-light buzzer, but why not put the stocking over the glow-lamp and dispense with the vacuum make-and-break?

It would be an odd cycle of events if acetylene, derived from calcium carbide made in an electric furnace, were to be used for driving a gas engine, say, to generate electric power. Dr. A. Frank, of Charlottenburg, however, has been investigating the advantages and disadvantages of this method of transmitting and obtaining power, and, in the *Journal für Gasbeleuchtung*, has given the results of his calculations. The basis of Dr. Frank's argument is that solid calcium carbide would be a cheap and convenient medium for the transmission of energy, the primary source of energy being a waterfall or some other not less cheap. He concludes that to obtain 1,000 H.P. for 25 days would require 295 tons of calcium carbide, as against 413 tons of coal, the latter being used for steam raising. The comparison is not devoid of interest, but it is woefully incomplete. The most flagrant omission is the absence of a comparison of costs, but perhaps —nay, certainly—this would have been less happy than the comparison of weights. Then again, Dr. Frank has ignored the possibility of using coal fuel in a gas engine, instead of raising steam; and his estimate of 1·543lb. (delightfully accurate though its four significant figures may be) of coal per horse-power-hour would be reduced to about 1·000lb. if a gas engine were used instead of a steam engine. Lastly, he has forgotten that Nature has provided us with a richer fuel than even calcium carbide in ordinary petroleum. To make the comparisons complete, therefore, we may add that about 267 tons of coal for gas power, and about 274 tons of petroleum for oil engines, would be the dynamical equivalent of the 295 tons of calcium carbide. We may take it, then, that it will be some time before the remarkable state of affairs mentioned at the beginning of this note will be brought about.

The Transfer of Trunk Telephone Lines.—It has not yet been found practicable to carry out the proposed transfer of the trunk telephone lines of the National Telephone Company to the Post Office Department on the 1st inst., as was originally proposed.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.

Church Struck by Lightning.—All Saints' Church, Sheffield, built through the munificence of Sir John Brown, was struck by lightning just before the afternoon service on Wednesday. The gas ignited and the chancel was soon in flames. Help was forthcoming, but the seat of the fire was got at with difficulty, and only just in time to prevent the flames consuming the valuable organ and fittings.

High-Volt Lamps for Edinburgh.—At Tuesday's meeting of the Electric Lighting Committee of the Edinburgh Town Council it was resolved to invite quotations from leading manufacturers for 10,000 high-voltage lamps, in view of the contemplated change to 230-volt lamps. It was further decided to obtain the opinion of the consulting engineer, Prof. A. B. W. Kennedy, so that the very best lamp in the market might be procured.

The "Benevolent Fund" of the Institution of Electrical Engineers.—Notice is given that a meeting of the donors and subscribers to the "Benevolent Fund" of the Institution of Electrical Engineers will be held at the offices of the Institution, 28, Victoria-street, Westminster, on Monday, February 3rd, at 4 p.m., for the purpose of considering, and, if approved, of adopting the draft rules which have been drawn up by a Committee of the Institution, and further for the election of a Committee of Management and officers in accordance with such rules as may be finally adopted.

Telegraphic Communication with South Africa and Ashanti.—The temporary interruption of communication by the West Coast route, to which reference has been made in the public Press during the last few days, was caused at Sierra Leone by the burning, on the part of the sanitary authorities, of a quantity of rubbish at the water's edge just where the shore ends of the cables from Bathurst and Accra are buried. The intense heat burnt the spun yarn serving of the cables, and completely melted the gutta percha insulation. No less than three sections were interrupted in this way, but repairs were promptly effected by the Superintendent, and the lines are now working well.

Crompton Arc Lamp Patent.—On Friday next will expire Patent No. 346 of 1882, granted to Rookes Evelyn Bell Crompton for "Improvements in Electric Lamps and Apparatus used in Connection with Electric Lighting." There are four claims, of which the first is as follows:—The use in an electric regulator lamp of a combination of a gearing frame moved by an electro-magnet or solenoid in the main circuit, with feed mechanism consisting of the brake wheel and parts operating therewith, which feed mechanism is set in motion by

Digitized by Google

the action of an electro-magnet or solenoid on a shunt or derived circuit, the whole forming a means of controlling the length of the arc substantially as described.

Institution of Junior Engineers.—At a meeting of the Institution of Junior Engineers, on the 10th inst., Prof. T. Hudson Beare, M.I.C.E., delivered a lecture on "Problems Connected with the Theory, Working and Testing of Gas Engines and Hot-Air Motors." In the course of his remarks Prof. Beare dealt with the use of regenerators for gas engines. He considered that possibly the efficiency could be increased, but at the cost of a bulkier engine for a given power. In regard to testing, it was shown that a complete thermal balance sheet of a gas engine can be obtained without direct measurement either of the volume of air or of the temperature of the exhaust, the temperature at the highest compression being the only assumption it would be necessary to make.

The Hopkinson Three-Wire Patent.—Notice is given that it is the intention of Dr. John Hopkinson and the Westinghouse Electric Company (Limited), of 32, Victoria-street, to present a petition to Her Majesty in Council, praying that Patent No. 3,576 of 1882 may be extended for a further term; and notice is further given that on February 24th next, or on such subsequent day as the Judicial Committee of Her Majesty's Privy Council shall appoint for that purpose, an application will be made to the Committee for a time to be fixed for hearing the petition; and any person desirous of being heard in opposition must enter a caveat to that effect in the Privy Council Office on or before February 24th next. This patent is the well-known three-wire patent, which would expire in the ordinary course of events on July 27th next. The claims of this patent as amended in June, 1891, are two in number. The first relates to the employment of "a differentially-wound indicating or regulating apparatus" to indicate when the difference potential between the positive and negative conductors at any point in a system of distribution differs from the normal by more than an assigned value, the generators being then automatically regulated accordingly. The second claim is as follows:—"In a system of electrical distribution or supply the employment of three (or more) conductors in combination with two (or more) dynamo-machines in series substantially as hereinbefore described with reference to Fig. 5 of the accompanying drawings whether the middle conductor be continuous or be replaced by an earth return, *as set forth*."

The Walthamstow and Epping Forest Railway.—At the last meeting of the Shoreditch Vestry the Electric Lighting Committee reported that they had had under consideration the question of entering into a contract to supply the London, Walthamstow and Epping Forest Railway Company with current for lighting their stations and tunnels. The engineers had fully reported on the subject, and it appeared that the Company will require about 420,000 Board of Trade units per year. This the Company will take purely as a day load, and will provide the necessary accumulators and all the subsidiary apparatus to enable them to supply themselves over the hours of heavy load, so that no extra plant would be required by the Vestry. The engineers estimated that the extra expense of running the machinery for this quantity of electricity would only amount to about £50 per annum, whereas the revenue at 1½d. per Board of Trade unit (the price recommended by the engineers) would be £2,625 per annum. In view, therefore, of the extremely beneficial effect of such a contract as this, which can be entered into at hardly any extra expenditure, the Committee decided to recommend "The Vestry to enter into a contract with the London, Walthamstow and Epping Forest Railway Company to supply them with electricity of a minimum amount of 300,000 Board of Trade units per annum, to be paid for whether they use this quantity or not, at 1½d. per Board of Trade unit on the above conditions, and to attach the Vestry's seal to the contract." The report was agreed to.

An Electrical Engineering Symposium.—The January issue of *Cassier's Magazine* is an "Electrical Number," and contains a wide variety of articles from the pens of frequent contributors to the American electrical press, not the least valuable feature of each article being a striking likeness of the author of it. The first contribution is a general-reader sort of discourse by Messrs. Houston and Kennelly on "Municipal Lighting from Underground Mains," the mains referred to being mostly Edison, and the municipal lighting mostly American. Dr. Louis Bell has a lucid little elementary article on "The Induction Motor," and articles on "Coalless Cities" and "Electricity for Propelling Railroad Trains at Very High Speeds," by Prof. F. B. Crocker and Mr. Hiram S. Maxim respectively, give the peeps into the future now so much in vogue. To English readers perhaps the most valued article will be that by Mr. R. E. B. Crompton on "Electrically-Operated Factories," in which he shows the immense saving (some 50 per cent.) which the thorough adoption of electric motors in engineering workshops would effect in the annual bill for the running and maintenance of the shop power-plant. Mr. Crompton also lays emphasis on the many side advantages offered by the presence of the electric current in the workshop, and his contribution, if it reaches those most concerned—*i.e.*, the owners of big engineering and similar shops—should prove of a very persuasive character. The "Electrical" number of *Cassier's* is a judicious blend of many sorts of information.

Electric Haulage Experiments on the Burgundy Canal.—Further electric haulage experiments are being carried on at the present moment on a selected section of the Burgundy Canal by the Société de Traction Electrique des Bateaux sur les Voies Navigables. Two modes of propulsion are being tested. Either an electrically-propelled iron boat is fixed to the sterns of the barges or they are *hauled* by a motor secured to a frame suspended from an overhead wire. The canal is 10 metres wide at the bottom and 1·8 metres deep, the draft of the barge, loaded to 186 tons (1,000 kilogramme ton), being about 1·5 metres. The current was supplied to the line at a pressure of 300 to 350 volts from a turbine-driven dynamo, the water used being, as described in a recent issue, that necessary to make good the losses by infiltration. Using the "bachot propulseur" and a barge 36 metres long with a square stern, the following results were obtained, the current varying from 12 to 14 amperes:—

Load (tons).	Speed (kilometre per hour).
100	3·0—0
150	2·7—2·8
180	2·5—2·6
230	2·3—2·4

With a more suitable type of barge, with a load of 70 tons, a speed of 4 kilometres was attained. The "electric horse" hauled two 200-ton barges at a speed of 2 kilometres an hour, the current varying from 10 to 12 amperes.

Contemporary Electrical Science.—As if in confirmation of Sauter's Paper referred to last week, the *American Journal of Science* gives particulars, furnished by Mr. O. C. Marsh, of a well-authenticated case of GLOBULAR LIGHTNING observed on board a yacht in Southampton Water. It fell slowly and directly from the mast on to the deck, and knocked down the mate, but not before he had observed that it was "four or five inches in diameter, and six or eight in length," and of a "delicate rose-pink colour." It dropped down a ventilator, "upset things generally in the culinary department," and finally exploded, but without doing any material damage or leaving any traces except a strong odour of ozone.—The *Proceedings* of the Physical Society for December contain, besides a most valuable NAME AND SUBJECT INDEX, some abstracts of Papers dealing with subjects recently treated in our columns. A model abstract is that of Grimaldi and Platania's Paper on the RESISTANCE OF COPPER WIRES IN PETROLEUM, which gives all the precautions and sources of error in a nutshell, and shows how Prof. Sanford's sensational observation concerning the influence of the dielectric is confirmed, but only to the extent of one-twelfth of its value. The quantitative result is, however, of much less importance than the qualitative.—In connection with Cardani's DETERMINATION OF THE RESISTANCE OF WIRES TO ALTERNATE CURRENTS, we find an abstract of Tuma's Paper from the *Wiener Berichte*. The heat developed in a thin-walled conducting tube formed by electro-deposition on a glass rod, was determined by a Bunsen ice calorimeter, with the help of machinery similar to Tesla's. The alternate-current resistance approaches the continuous-current resistance as the specific resistance increases, and the ratio of the two increases with the thickness of the conductor and the frequency of the current.

THE CROMPTON POTENTIOMETER: ITS USE AND CAPABILITIES.—III.*

BY W. C. FISHER, ASSOC.MEM.INST.C.E.

There being no other points in connection with the main instrument to which attention need be drawn for the present, the writer turns to the consideration of the different adjuncts necessary to complete this system of measurement.

The first item of interest is naturally the source of the main E.M.F., as it is upon the constancy of the E.M.F. at the terminals of the instrument that expeditious measurement depends, for whilst it may always easily be checked and adjusted by reference to the standard, the time spent in so doing, if of frequent occurrence, is of material importance when a continuous succession of readings have to be taken at very small intervals of time. Ordinary primary batteries are too trouble-

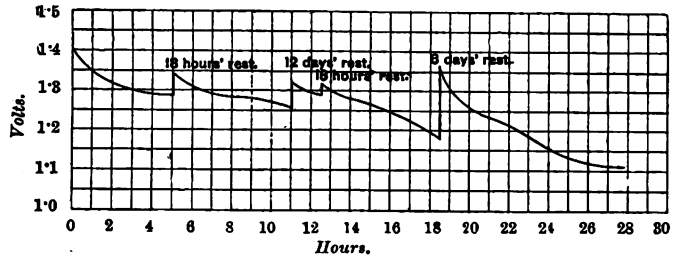

FIG. 11.—Obach Dry Cell. Average fall in E.M.F.=0·0037 volts in 10 minutes.

some to admit of their being tried, even experimentally, whilst of the many types of dry batteries experiments and experience show that the fall of E.M.F. is far too rapid to admit of their use. The following curves (Figs. 11 and 12) of the "E.C.C." and Obach dry cells—admittedly the best—prove this beyond any doubt. The size of the cells tried was that which approximated in weight to that of the secondary cell usually used for portable work, although two of them would be necessary to obtain the requisite voltage for use. They were placed upon a circuit equivalent in resistance to the potentiometer, and the fall in E.M.F. with time noted. It is a matter of regret that this rapid fall should take place, as they would be of inestimable use on account of their portability. When one has to roam the country testing plant the inevitable and apparently unpreventable leakage of electrolyte in a secondary cell, if carried about

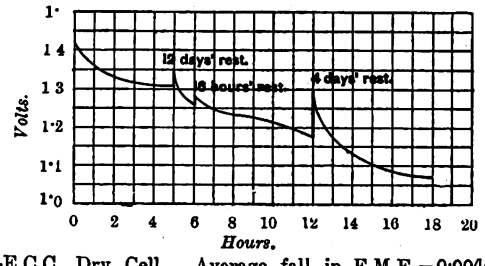

FIG. 12.—E.C.C. Dry Cell. Average fall in E.M.F.=0·0046 volts in 10 minutes.

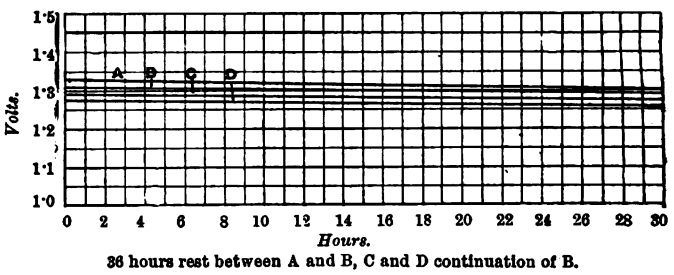
full, and the nuisance of preparing or adding electrolyte at one's destination, if empty, is very annoying, and is a matter that requires some improvement; to this has to be added the want at times of facilities for charging.

But where the instrument is a fixture the secondary battery is *facile princeps* the source of E.M.F. best adapted—given adequate means of charging the same. The fall in E.M.F. when what is termed the flat portion of the discharge curve is reached is so very small for quite long intervals of time as to be almost negligible for any but the most careful and accurate tests in the case of the size cell usually adopted it amounts to less than $\frac{4}{10000}$th of a volt in 15 minutes or thereabouts. Fig. 13 is a curve of the E.M.F. of such a cell used with the potentiometer described. It is to the same scale as Figs. 11 and 12, the test being carried out in a similar manner; it shows strikingly the difference existing between them in the most essential point desired.

Where the instrument is stationary it is also an advantage to have secondary cells of fairly large capacity, say 15 or 20 ampere-hours, so that the current may always be left on the instrument, and the consequent wait for the E.M.F. to settle down when first connected is so avoided. By adopting this plan the instrument is always ready for working throughout the week, the charging of such cells being made at a slow rate over the week end. To save time after a full charge, it is expedient to get rid of the initial voltage by partially discharging through a low resistance for a short time, in that manner steadying the cells. The constant charge and discharge of the cells, as mentioned above, is also productive of good, inasmuch as it tends to keep them in a healthy condition, for nothing is more irritating, especially when engaged upon careful or accurate work, such as the comparison of resistance standards, than a cell which tends to be at all in an unhealthy condition. Internal disturbances in the cell make themselves so very manifest in the behaviour of a sensitive galvanometer by a series of spasmodic jerks and kicks, the worst phase of the same being when they are of an intermittent nature; they then invariably put in an appearance just as one is in the act of completing a very careful measurement, so spoiling the result and ruining the most tranquil of dispositions. Continuous "gassing" of the cell is very productive of this source of annoyance; a cell which bubbles slightly, whether at rest or at work, is useless for delicate measurements, as every bubble off the plates is heralded by a slight kick in the galvanometer, whilst a stream of bubbles sets the mirror dancing.

Here a word of warning is necessary. *Never under any circumstances connect the instrument to one of a number of cells in series;*



36 hours rest between A and B, C and D continuation of B.

FIG. 13.—Secondary Cell. Average fall in E.M.F.=0·0008 volts in 10 minutes.

always use an isolated cell. If this is not attended to accidents are sure to happen, with resultant injury to the instrument. Several instances have occurred in which this has been done with disastrous consequences. Upon two, if not three occasions, incredible as it may appear, use was made of the milking cells of a central-station battery. An attempt to measure current or volts obtained off the same system of supply naturally resulted in "instrumental fireworks;" in the one case 100 volts, and in the second case 220 volts did something more than spoil the calibration of the instrument. A systematic use of fine fuses or fuse wire is strongly to be recommended.

The Galvanometer.

The potentiometer method of measurement being a null or zero method, the only points to be considered with reference to the galvanometer in ordinary work such as that obtained in central stations, are deadbeatness, commensurate sensibility, and freedom from vibration, together with freedom from interference of stray magnetic fields. For these reasons the so-called "D'Arsonval instrument" is usually employed, as more nearly fulfilling the specified points. Under some circumstances—where the time element is of no importance—the Thomson or Kelvin mirror galvanometer may be used. There is one case on record where, a test having to be made in a northern city, such an instrument *had* to be used, an accident having happened to the D'Arsonval instrument in transit. An endeavour was made to borrow one, but whilst almost every other philosophical instrument was obtainable, a D'Arsonval galvanometer was unknown.

The D'Arsonval instrument is nothing more than the Thomson or Kelvin recorder condensed and rendered more

sensitive. Briefly described, it may be said to consist of a rectangular coil of fine wire freely suspended in a magnetic field, in which it normally rests in a direct line with the poles, but upon the passage of the current it tends to set itself at right angles with the poles, the amount of deflection being dependent upon the current passing. The instrument is dead-beat—that is to say, it comes, or can be brought, to rest very quickly. It is therefore of great value when quick working is desirable. Its sensibility should be somewhat commensurate with that of the potentiometer—that is to say, it should be such that with unit movement off balance on the potentiometer there should be at least two or three times that amount of movement of the galvanometer spot off zero. With reference to vibration, it is a matter purely of circumstances; where special means can be adopted to prevent communication of the cause, it should not be a source of trouble; where such means are not available, or, when tried, are not successful, in some makes of this type of instrument it may be obviated in a manner which will be mentioned later on.

It is usual with this type of instrument to read the deflection by means of a spot of light reflected off a small mirror attached to the coil, but a pointer of medium length attached to the coil is, when ordinary accuracy only is required, all that is necessary.

With reference to a reflected spot, it is usual to project it upon a wall or stand usually at some distance from the eyes. This is much to be deprecated, as the strain upon the eyesight is great with continued testing, more especially as in order to work effectively there should be semi-darkness; what is far more preferable and pleasant to work with is a portion of the image of an incandescent lamp filament thrown from the mirror on to the back of a piece of ground glass placed immediately opposite and close to the operator and on a level with his eyes; in this manner semi-darkness is avoided, together with smarting of the eyeballs, and the spot is easily discernible upon the brightest day.

Of the D'Arsonval type of instrument there are many makers, the majority of whom have faithfully followed in each other's footsteps in an endeavour to produce an instrument of the pattern originally adopted by Carpentier, of Paris, which consists of a compound magnet of U-form placed vertically upon a base, and between the poles of which a rectangular coil of copper wire is suspended from an overhanging arm by means of a fine silver wire; a similar wire attached below the coil keeps the whole taut by being fastened to an adjustable spring. The true Carpentier instrument has a sensibility beyond the average, the magnets being very powerful; but if the silver wire be removed, and a fine phosphor-bronze strip similar to that used by Prof. Ayrton be put in its place, the sensibility is invariably increased twentyfold.

The first deviation from this form *in the market* was that introduced by Messrs. Ayrton and Mather, who abandoned the vertical magnet, rectangular coil and strain upon bottom connection, substituting a circular or cylindrical magnet with very small air gap, and pushing the recorder or shuttle-shaped coil to the extreme, they adopted a closed loop, a cross-section of which might be represented by the figure 8. This is enclosed in a silver tube and suspended from above by a flat strip suspension in the very intense field obtained by their form of magnet. The bottom connection is a loose spiral of fine strip. The degree of sensibility obtained has been put at various figures, but the writer is assured by Prof. Ayrton that an instrument constructed and in use at the Central Institution is capable of a 2mm. deflection at 2,000mm. distance, with one-millionth of a volt at its terminals. This figure of merit is the more remarkable, inasmuch as the coil is hampered by considerable magnetic control, having been constructed before means were found of freeing it from the same.

The Ayrton-Mather instrument, as constructed by Messrs. Paul, is exceedingly neat and compact. A description is not necessary, as it is well known. It has but one inherent defect, which is not so much due to design as to principle: the fact of the coil being suspended from above with a short suspension with no strain from below to steady it, renders it exceedingly susceptible to vibration *where any exists*, especially if caused by rapidly-revolving machinery.

Major Holden has also designed a very compact and efficient instrument, made by Messrs. Pitkin. The most striking features are the smallness of the compound magnet and its great lamination, consisting as it does of a number of thin horseshoe discs clamped together. The coil is square-shaped and strained in position upon a frame which is easily removable for the introduction of a coil of different resistance, &c., as is also the case with the Ayrton and Mather instrument.

FIG. 14.

For delicate work the potentiometer method of measurement requires a galvanometer which differs from that ordinarily employed, inasmuch as it should be one that is exceedingly sensitive at zero point only, evenness or length of range being unnecessary. Up to the present, so far as the writer is aware, D'Arsonval instruments have invariably been designed for *deflection* work, the magnetic field accordingly being shaped so that the instrument has a scale of equal divisions. An extended use of the potentiometer, and an inquiry into its capabilities,

Digitized by Google

brought out sundry important points in connection with very accurate work which necessitated a study of the galvanometer question, and resulted in the design of a galvanometer having the following points:—

1° Perfect insulation;

2° Maximum sensibility off zero with minimum voltage on terminals;

3° A sensibility alterable at will;

4° Coils easily interchangeable;

5° Solidity in mechanical construction, and the whole open to instant inspection;

6° Absolute freedom from ordinary vibration.

Plan.

FIG. 15.

The instrument depicted (⅓rd full size) in Fig. 15 was designed after several years patient investigation in Mr. Crompton's laboratory, and, having been recently fully described in these columns, needs but a brief description at present. Upon a gun-metal base of section shown, supported upon three levelling screws having ebonite milled heads of inverted pyramid shape, a compound horseshoe magnet is bolted down. From the centre of the base springs a pillar of tubular section, which is surmounted by a cap capable of vertical adjustment by means of the milled head shown at top, radial movement being prevented by the small set screw at side, which slides in a groove in the pillar. Encircling the cap is a sleeve, attached to which is an arm having a second but smaller sleeve at the end. This arm has a radial movement round the cap for necessary adjustment, being clamped in position by set screw at side; in the small sleeve is fitted an ebonite turntable carrying the small terminals, to which the suspensions are attached by means of taper plugs, connection with the main terminals upon the base of the instrument being made by means of insulated wires carried down inside the central pillar. A thin vane of ivory, fixed in a projecting pin having a milled rim, and free to turn on its axis in a sleeve capable of radial and vertical adjustment upon the pillar, and which may be clamped in any position, is the means adopted for altering the sensibility of the instrument by artificially lowering the point of suspension.

Fig. 16 (⅔rds full size) represents a smaller or more portable type of this instrument, practically similar to No. 15, but simpler in construction. The magnets are of the Holden type (being adopted by Major Holden's kind permission); the holding-down bolts are carried through the base and shod with the ebonite levelling shoes shown. The coil has a bifilar suspension, which is attached by means of two plugs to two brass blocks fixed upon an insulated bracket upon the central pillar. There is a simple clamping device, not wholly shown, which effectually secures the coil from injury whilst travelling. It may be of interest to point out that the instrument is protected by a brass guard having a bevilled glass front similar to the larger instrument; an annular ring upon the guard carries a thick glass tube having a brass cap, the whole being effectually clamped together by the milled nut which surmounts the instrument. The whole is very strong, handy and compact, going comfortably into a coat pocket, and it has the great advantage, possessed also by the larger instrument, of being open to inspection, so that the position of the coil is readily observable without that peering into almost obscurity common in the use of many instruments of this type. This instrument has a sensibility ordinarily of 2mm. at 2,000mm. distance when placed in shunt with $\frac{1}{100}$th of an ohm in series with 20,000 ohms and 2 volts, having therefore a potential of $\frac{1}{1000000}$ volt at its terminals, and a period of 2 seconds; the larger instrument under similar conditions having a sensibility six or eight times greater but slower period.

CALCIUM CARBIDE.

The first calcic carbide plant to [illegible] purposes in America, as a result [illegible] Mr. T. L. Willson, in North Carolina, [illegible] nearing completion on the land of the Niagara [illegible] Company. The product of this initial plant will be shipped to Philadelphia, Pa., and there made into acetylene gas for use throughout that city and Southern Pennsylvania. At the start it will be necessary to ascertain the amount of electric energy which will prove the most economical for a given output. So far the experiments have only been made with from 25 H.P. to 235 H.P. The contract of the Company with the Niagara Falls Power Company calls for 1,000 H.P. or more. One feature of the plant is that an alternating-current furnace is to be used, whereas all the other electric manufacturing plants at Niagara Falls use direct-current furnaces. The current will be used at a voltage of about 100. At the commencement it is likely that the furnace will be operated by 100 H.P. to 1,000 H.P.

The size of the first carbide plant is 40ft. by 90ft. at the foundations. The structure is of brick, the front portion being two storeys high, or 31ft. to the eaves, while the rear part is 21ft. It contains a furnace room, a crushing and grinding room, a laboratory, a switchboard room, a transformer room,

Digitized by Google

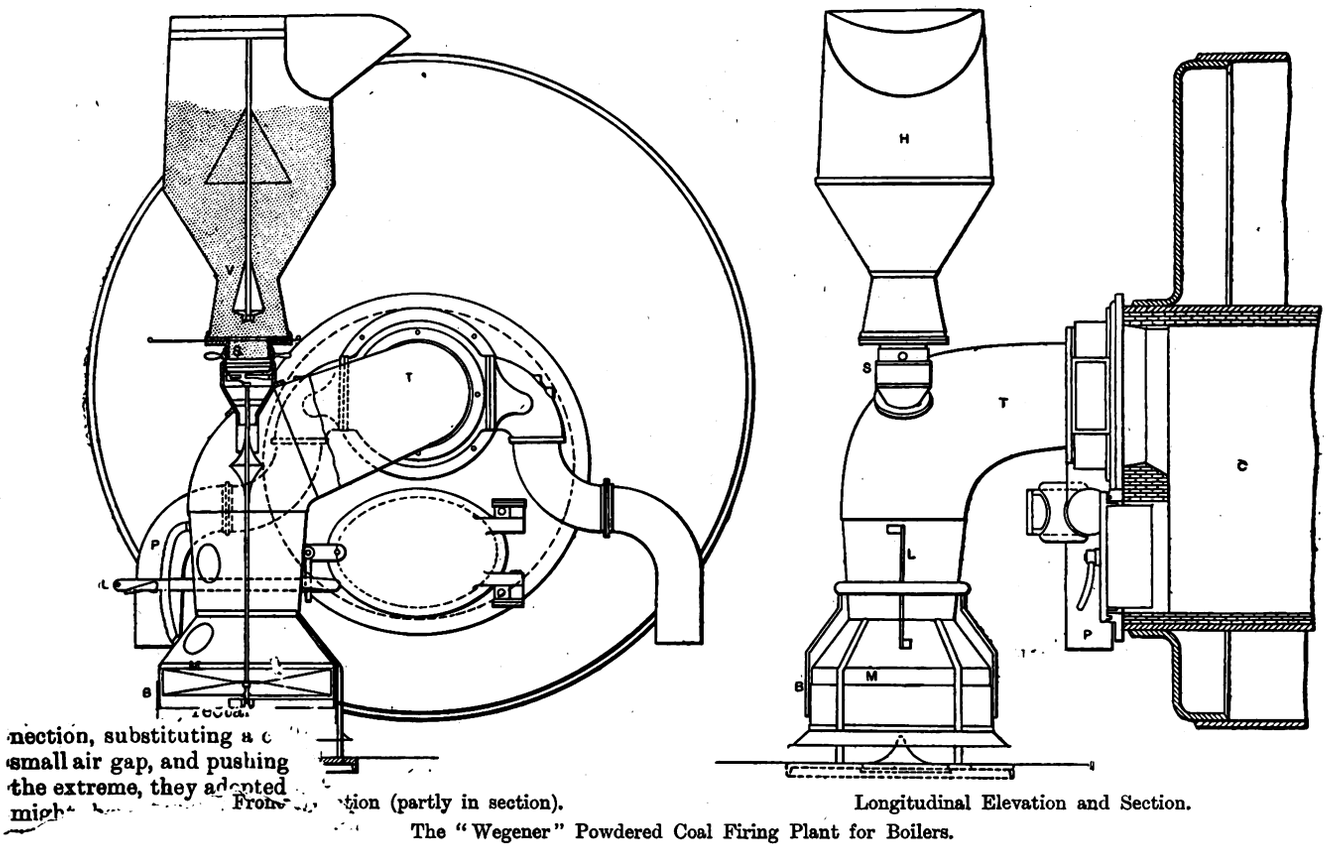
and a room for the help employed. The crushing and grinding portion of the outfit is to be of sufficient capacity to supply a plant of 50 tons capacity, whereas the capacity of the plant at the start will be at least five tons per day. A two-phase 75 H.P. motor will operate the grinding plant. In the furnace room four furnaces have been built, each containing cast-iron crucibles 3ft. 6in. long, 2ft. 8in. deep, and 2ft. 2in. wide. The current will be kept on each furnace for about three hours, one furnace being operated at a time. Each horse-power used is supposed to give 20lb. of calcic carbide every 24 hours.

It is thought altogether likely that calcium carbide will be manufactured by the Niagara plant at a cost not exceeding $5 per ton. The factory is expected to be in operation by the beginning of February.

POWDERED COAL FOR STEAM RAISING.

One of the most ingenious and, so far as we have been able to ascertain, economical systems for utilising breeze, smudge, and other cheap qualities of slack coal is that which is known as the "Wegener" process. Recently we had an opportunity of inspecting this system in operation at the boiler house of Messrs. Bryan, Donkin and Co.'s engineering works at Bermondsey. The extreme cheapness of most qualities of dust coal is a great temptation to use them for steam raising, but the results obtained are often far less satisfactory and economical than where good round coal is used. Finely divided coal is not easily burned on a grate, owing chiefly to the difficulty of supplying the fuel with air in an efficient manner. This difficulty is surmounted, in the "Wegener" process, by doing away with a grate, and by blowing the fuel in suspension in air into the closed combustion chamber of the boiler furnace. It is well known that finely-divided coal suspended in the right proportion of air is so inflammable as to be practically explosive, and in the "Wegener" process the firing is carried on by a quick succession of puffs of coal-dusty air into the furnace, producing a series of mild explosions. A little window in the boiler front enables these explosive flares-up to be watched for purposes of regulation.

The manner of producing the charge of fuel and air will be understood by examining the accompanying longitudinal and transverse sections of the plant, shown attached to a Cornish boiler front. In the hopper, H, the finely-divided coal is placed. The coal has previously been ground to powder, and passed through a 60-mesh sieve. A lift valve, V, enables the orifice at the bottom of the hopper to be partially or completely closed. When this orifice is open the dust coal rests upon a shaking sieve, S, which consists of a circular grid. While this sieve is not in motion the coal clogs on the top of the sieve and does not feed downwards; but when the sieve is tapped, by a mechanism provided for the purpose, a small portion of coal will tumble through in a kind of spray. The number of these taps per minute can be regulated to a nicety, and will control the rate of firing into the boiler furnace. To understand how the taps are produced we must turn to the lower part of the apparatus. At B there is a bell-mouth, suspended over a floor plate so as to provide an annular passage for the air into the apparatus. The height of this bell regulates the supply of air, and is adjusted by means of the lever and ratchet L. The air is drawn in by the natural chimney draught, which in the case of the boilers we inspected was a little under $\frac{3}{8}$in. of water. It will be noticed that inside the bell, and near the bottom of it, is a set of vanes forming an air motor, M, and this is set in revolution by the up passage of the air. The spindle of this motor passes up through the air up-take tube and actuates a tappet, which provides the quick succession of taps upon the sieve S, necessary to the continuous downpour of dust coal.



nection, substituting a c
small air gap, and pushing
the extreme, they adopted
mich[illegible] From[illegible]tion (partly in section). Longitudinal Elevation and Section.

The "Wegener" Powdered Coal Firing Plant for Boilers.

The shower of coal in its descent meets the uprising rush of air, mingles with it, and passes on in a highly inflammable mixture through the tube T into the brick-lined combustion chamber C. The effect is to fill the chamber with a large volume of flame, and the mixture of the coal and air being so intimate, combustion is both rapid and complete. Moreover, owing to the finely-divided state of the coal in suspension in the air, a lower proportion of air is required, *i.e.*, less surplus air is necessary than where round coal is burnt on a grate. This, it will be seen, cannot fail to enhance the economy of the process. The mineral matter in the fuel forms a fluid slag which falls to the bottom of the flame chamber and is removed when the boiler has been shut down. Ordinarily, of course, the boiler front is completely closed. When highly bituminous coals are to be burned, an extra supply of air beyond that

Digitized by Google

entering through the bell is necessary to ensure complete and smokeless combustion. This is provided by means of the auxiliary air inlet pipe P, which is fitted with a regulator valve.

We have not had the opportunity of conducting any trials of this system, but we are assured that a high rate of evaporation is obtained by means of it, and we are quite prepared to credit the statement. The boilers which we saw were of the Lancashire type, and were fitted with two of these "Wegener" fuel plants. Cold feed at 62°F. was taking place, and an evaporation at 60lb. pressure of from 7·5lb. to 8lb. of water per pound of coal (as used) was obtained. The cost of treating the small coal so as to render it suitable for firing by this process is not, it is stated, more than about 10 per cent. of the price of the coal. Taking the average price of these classes of coal, the cost of treatment would be about one shilling or less per ton. The initial cost of the plant, not including the crusher, is about £100 for a double-furnace boiler of large or moderate capacity.

THE ALUMINIUM WORKS OF THE PITTSBURG REDUCTION COMPANY AT NIAGARA FALLS.

BY ORRIN E. DUNLAP.

The Pittsburg Reduction Company is practically the only manufacturer of aluminium in the United States; it controls and uses what is known as the Hall process, the invention of Mr. Charles M. Hall, who is now vice-president of the Company. This process of manufacture consists in dissolving alumina in a molten bath composed of fluoride of aluminium and the fluoride of some metal more electro-positive than aluminium. An electric current is passed through the molten mass, and aluminium is produced by electrolysis of the dissolved alumina. The fluorides of potassium and of calcium, with the fluoride of aluminium, are the most preferable salts used in the molten bath, although the fluoride of aluminium with the fluoride of sodium have been successfully used by the Pittsburg Reduction Company in much of their work. The double fluoride of aluminium and potassium is made by the action of hydrofluoric acid upon alumina and pearl ash or carbonate of potassium. The fluoride of calcium is obtained from the mineral fluorspar. When the Pittsburg Reduction Company use the fluoride of sodium they have in the past used largely the native mineral cryolite as the source of this portion of the salts, although of late improvements have been made by which cheaper methods of producing the double salts of fluorides of aluminium and sodium have been obtained.

In the present plant at Niagara Falls the Pittsburg Reduction Company have two lines of carbon-lined iron pots, arranged in series, and it is in these pots that the chemicals are placed. The electric current is passed through the molten mass by the aid of carbon cylinders used as anodes, which extend down into the molten metal. The pots themselves, with their lining and the metal deposited upon the bottom, becoming the negative electrodes or cathodes, the alumina is deposited by electrolysis in a molten mass at the bottom of the pot. The freed oxygen goes out as carbonic oxide or carbonic acid gas in connection with the carbon of the anode, wearing it away in proportion of a little less than an equal weight of the anode to the aluminium produced. The operation is kept continuous for months at a time, as the wear upon the pots is very slight, the metal being dipped out from the pots each day by heavy cast-iron ladles. In some countries the makers of aluminium are greatly troubled with noxious gases, and their employés work only for very short periods. The Pittsburg Reduction Company, however, owing to the advantages of the special chemical solvents which they use for dissolving the alumina and the particular strengths of current adopted, are not, it is said, troubled in this way, there being practically no discharge of other noxious gases into the atmosphere, practically the only gas evolved being carbonic acid. Now and then a carbon will heat above the bath and sputter out in a dark blue flame, showing the burning of carbonic oxide to carbonic acid gas.

In the Pittsburg Reduction Company's work, of course, very large currents at low voltage are used, the pressure required being only enough to overcome the electrical resistance of the number of pots arranged in series, each pot now in use requiring from 6 to 8 volts. The power used by the Pittsburg Reduction Company is supplied by the Niagara Falls Power Company, on the two-phase system, at 2,000 volts pressure. It is conducted from the power house to the factory on copper cables laid in a subway. In the manufacture of aluminium it is necessary that this current should be reduced as well as transformed from alternating to direct. By means of the static transformers shown in the illustrations (Figs. 1, 2 and 3), the voltage is reduced from 2,000 to 115, and the rotary converters shown change the current from the two-phase alternating variety of 115 volts to a direct current of 160 volts. The electrical equipment of the Reduction Company's plant was furnished by the General Electric Company of Schenectady. The rotary converter is practically a direct-current generator with proper collecting rings and connections attached to the rear of the armature to lead the alternating current into the apparatus. The Pittsburg Reduction Company's present electrical plant has a capacity of about 10,000 amperes at 160 volts, or 1,600 kilowatts, or about 2,000 E.H.P. on the direct-current side. In the static transformer,

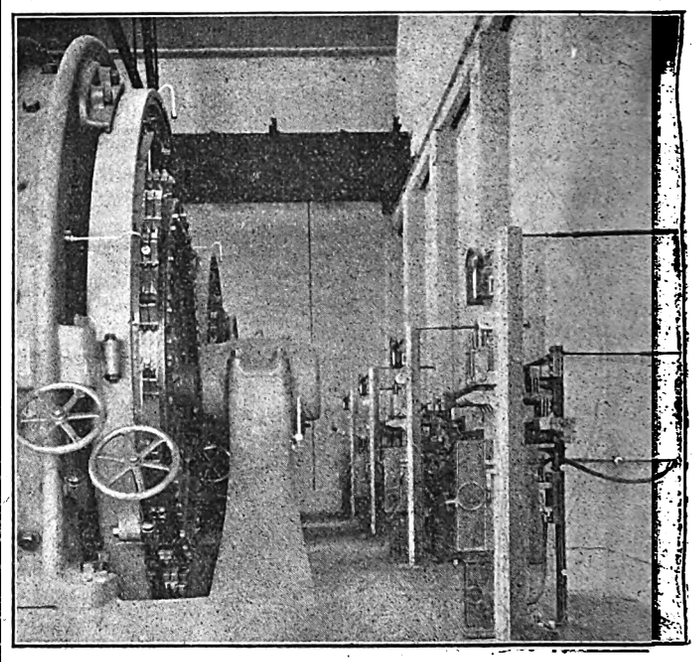


FIG. 2.—Direct-current Side of the Rotary Converters and the Low pressure Switchboards.

notwithstanding its high efficiency, the energy transformed into heat is so great that there is not sufficient radiating surface to throw it off. For this reason an air-blast is forced continuously between the coils from below, thus keeping the heat easily under control.

There is a commonly-accepted notion that clays are the ores of aluminium. The Pittsburg Reduction Company do not use clays, which are silicates of aluminium, in the manufacture of the metal, but the pure oxide of aluminium, called alumina, which is made from the native oxide of the metal in a mineral known as bauxite. This mineral is found in large deposits in Georgia and Alabama, and it is from these States that the Pittsburg Reduction Company secure their supply, they finding it possible to lay the ore down at their factory in Niagara Falls at a low rate. The bauxite belt of Georgia and Alabama extends in a north-easterly and south-westerly direction, its length being about 75 miles and its width about ten miles. The ore is found in pockets at the top of the Knox dolomite of the lower Silurian rocks in both of the States mentioned. It is noticeable that the bauxite ores in the United States are all in sections of the country which have been broken up by sharp folds and great thrust

Digitized by Google

faults, in which the character of the rock has been greatly changed, probably the result of intense heat. The bauxite ores of Georgia and Alabama are associated with the manganese and iron ores, which similarly occur in the same district in "pocket" formations.

This ore exists in several peculiar forms, as follows:—(1) In round nodules, some of these being in sizes up to 2in. in diameter, and each nodule being separated from its fellows. (2) An agglomeration of these nodules into a conglomerate, the binding material between the nodules being pure alumina

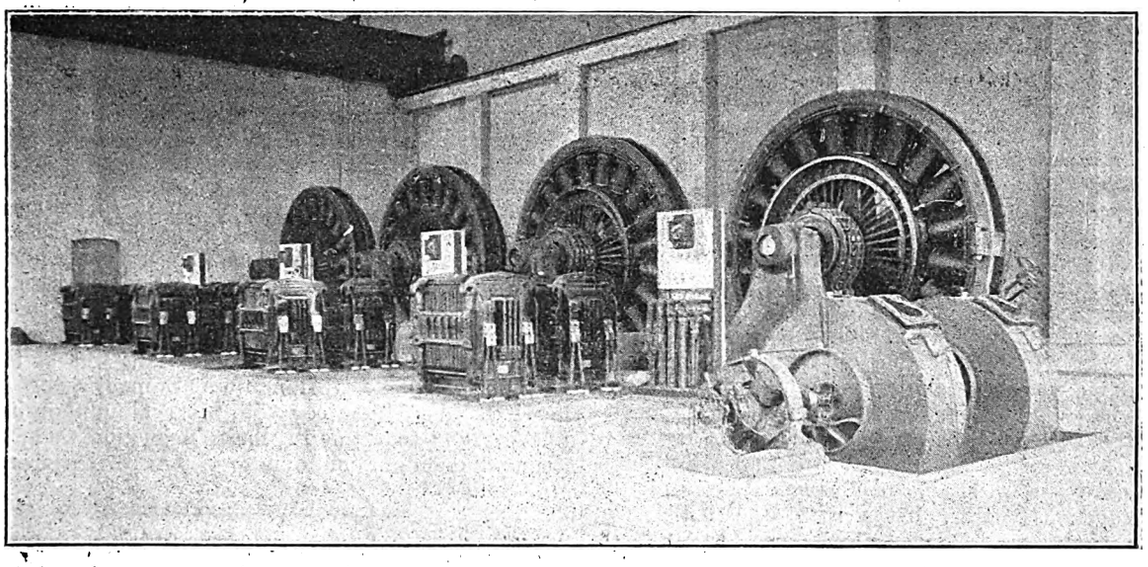

FIG. 1.—The Electric Plant of the Pittsburg Reduction Company at Niagara Falls.

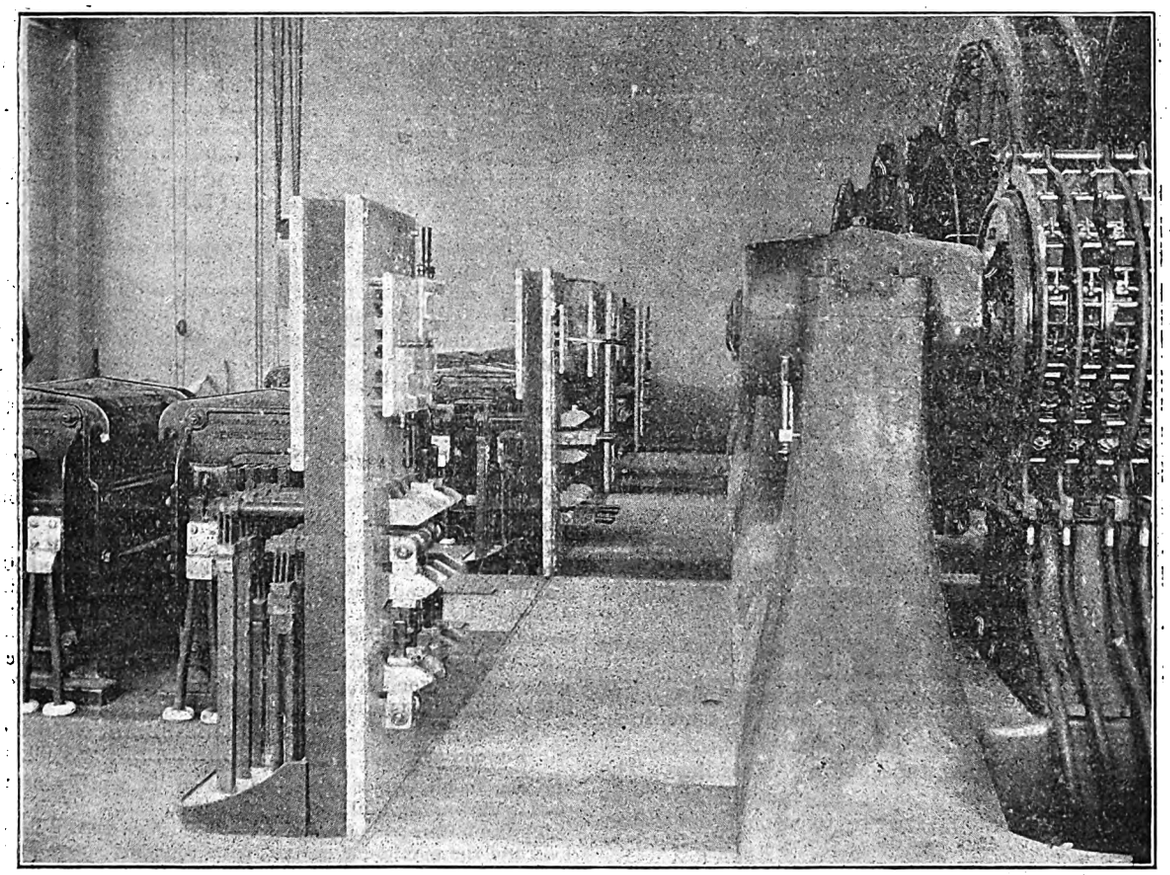

FIG. 3.—The Alternating-current Side of the Rotary Converters, the Static Transformers, and Alternating-current Switchboards.

The composition of the bauxite best adapted for the manufacture of alumina is as follows:—

Silica	3·00	per cent.
Titanic acid	4·00	,,
Oxide of iron	2·00	,,
Water of hydration	32·00	,,
Alumina	59·00	,,
Total	100·00	per cent.

(3) A massive formation. (4) A fine powdered condition in the beds at the banks, being mined in the form of plastic mud.

To form aluminate of soda, it only need be incinerated lightly with soda ash. This aluminate of soda is dissolved and decanted off and freed from the impurities of silica, oxide of iron and titanic acid which have not been acted upon and are insoluble in the hot water used for solution of the alumi-

Digitized by Google

nate of soda. It is from this solution alumina is precipitated by passing carbonic acid, formed by the distillation of carbonic acid from limestone, through the solution, and also by agitation. The carbonic acid reforms carbonate of soda from the aluminate, and precipitates the pure aluminum very freely. This settles at the bottom of the tank, and after being thoroughly washed with hot water and then dried, it is heated for some time at a high red heat, to drive off the water of hydration, which makes the ore ready for the production of aluminium by the Hall process.

So successful has been the Pittsburg Reduction Company's plant at Niagara Falls that, although it was only started on August 26, 1895, the Company have already taken steps to double its plant. The plant, as erected with the Niagara Falls Power Company, was planned for doubling the capacity in the same buildings, and the contract arrangements which the Pittsburg Reduction Company has with the Niagara Falls Power Company are that it has the right to call for additional power up to any capacity that is unsold by the Niagara Falls Power Company at the time when such power may be asked for; so that the Pittsburg Reduction Company enjoys the right to enlarge its works almost indefinitely at comparatively very small cost for installation of new plant, as the capacity of the Niagara Falls Power Company and its rights to the use of water-power at Niagara are practically illimitable. Besides these favourable arrangements, however, the Pittsburg Reduction Company has contracted with the rival water-power company at Niagara Falls, the Niagara Falls Hydraulic Power and Manufacturing Company, for 4,500 E.H.P. additional. This plant is now progressing rapidly, and will be completed in the early spring. Thus the Pittsburg Reduction Company is in a position to enlarge its plant for the use of the Niagara power from both large water-power sources—one the Niagara Falls Power Company using the tunnel, and the other the Niagara Falls Hydraulic Power and Manufacturing Company using the hydraulic canal going through the city of Niagara Falls. This 4,500 H.P. will be used in a factory, now in course of construction, on the high bank of the gorge; thus the Company will have what is known as an upper and a lower works, one being on the upper river above the falls, and the other below the cataract. The plant in the new or lower works will consist of dynamos directly attached to the turbine shafts. These generators will be of 750 E.H.P. each, the turbines being furnished by the James Leffel Company, Springfield, O. In this plant the electric current will be transmitted from the power house at the water's edge in the gorge to the pot room in the factory on the high bank above on *aluminium* conductors. This new plant will be ready for operation next spring, and it is officially stated that by June 1, 1896, the Pittsburg Reduction Company expect to be making 10,000lb. of aluminium per day at Niagara Falls.

In addition to the plant manufacturing aluminium at Niagara Falls, the Pittsburg Reduction Company has, of course, its old plant of some 2,000 E.H.P. successfully working in the manufacture of aluminium at New Kensington, Westmoreland County, Pennsylvania. This plant is especially located for generating steam power economically.

The product of the Niagara plant is now being shipped in ingot form to the New Kensington Works, where the foundries, rolling mills, and hammer shops are located for forming the metal into sheets, bars, plates, tubes, wire and castings. The Pittsburg Reduction Company does not manufacture any articles of aluminium, as it does not care to become competitors of its own customers.

It is a significant fact of the efficacy of the cheap electric power of Niagara that it is a successful competitor of the Kensington plant. The latter factory is located most favourably in the heart of both the natural gas and cheap coal fuel districts which have made Pennsylvania famous, and the Pittsburg Reduction Company buys coal delivered at their boilers for 65 cents a ton, still it has found their Niagara location more advantageous.

When it is considered that this Company within a few months will be turning out 10,000lb. of aluminium a day, its importance to the industry is best shown by a table showing the product of aluminium in the United States each year since 1882, which is as follows:—

Year.	Lbs.	Year.	Lbs.
1883	83	1889	47,468
1884	150	1890	61,281
1885	263	1891	1[illegible]0,000
1886	3,000	1892	259,385
1887	18,000	1893	339,629
1888	19,000	1894	550,000

The total output in the United States for 1895 will reach about 850,000lb. The output for 1896, it is estimated, will be fully 10,000lb. a day for the 366 days of the year, or a total of 3,660,000lb., which (if it happens) will be the most notable increase in the output during any one year since aluminium was discovered.

The latest price list of the Pittsburg Reduction Company quotes aluminium, guaranteed to be 98 per cent. pure, at 55 cents per pound in small lots, 52 cents per pound in 100lb. lots, and 50 cents per pound in ton lots, which price is likely to be reduced next year. It was in 1885 that the first step towards the manufacture of aluminium for industrial purposes was taken in the United States. This was in the Cowles Electric Smelting and Aluminium Company's works in Cleveland, O., where they began to make aluminium-bronze. It was in 1888 that the Pittsburg Reduction Company began the production of aluminium for commercial purposes by the Hall process.

TRIALS OF ALTERNATE-CURRENT PLANT AT DOVER ELECTRIC SUPPLY STATION.*

The tests described in the following report had as object the determination of the capacity and efficiency of supplied by the Brush Electrical Engineering Company (Limited) to the Dover Electricity Supply Company (Limited) under a memorandum of agreement and specifications dated November 20, 1892.

The chief conditions in the specification affecting the capacity and efficiency of the plant were the following:—

1. The output of the alternators to be 50 kilowatts, 75 kilowatts and 100 kilowatts respectively at an E.M.F. of from 2,000 volts to 2,200 volts.

2. The output of each of the two exciters to be 12·4 kilowatts, or, say, 190 amperes at 65 volts.

3. The output of each of the two feed-pumping engines to be equivalent to the full power of all the boilers.

4. The combined efficiency of the steam alternators to be 78 per cent. for the 50-kilowatt and 75-kilowatt sets, and 80 per cent. for the 100-kilowatt set.

5. The steam consumption of the engines at full load not to exceed 19·5lb. of water per I.H.P. hour for the 50-kilowatt set, 19lb. for the 75-kilowatt set, and 18·5lb. for the 100-kilowatt set.

6. The energy absorbed in exciting the field-magnets of the alternators not to exceed 2½ per cent. of the full output of the generators.

7. After a six-hours continuous run at full output the temperature of no part of the armature or magnets is to exceed 60°F. above that of the atmosphere of the engine house taken one minute after stopping the machine, on the side remote from the engine, and at no time to exceed 90°F. above the temperature of the atmosphere.

8. The insulation resistance between the whole of the conductors and the framework of the generator taken before and after a test at full load at any time not to be less than

For the armature ..... 500,000 ohms,
For the magnets ..... 400,000 ohms,

and the insulation of the armature to be capable of resisting a testing current at 4,500 volts alternating.

9. The fall in potential on a non-inductive circuit between half-load and the maximum output, with constant speed and constant excitation, not to exceed 150 volts.

10. Each of the main engines and alternators and the exciter engines and exciters to be subjected to a six-hours continuous trial at full load, and subsequently the two exciters to be tested in parallel with each other, and in like manner all the alternators to be tested in parallel with each other, for two consecutive hours on from three-quarters to full load.

11. The circulating and feed pumps and engines connected to them to be tested at full working capacity for six consecutive hours.

* Extracts from a report by Profs. A. B. W. Kennedy and S. P. Thompson, FF.R.S., forwarded to us by the Brush Electrical Engineering Company.—Ed. *E.*

The tests took place in the station at Dover on October 7th, 8th, 9th, 10th, and 11th last, and were carried out by ourselves and a special staff of trained observers, whom we sent down to Dover for the purpose. The leading results of the experiments are set forth in the annexed tables; and on the whole matters referred to we have to add the following remarks, taking up the various points in the order in which they have been enumerated above:—

1. No. 4 set was tested first at various loads, and finally during a continuous run of six hours at full power (50 amperes at 2,000 volts). *The next morning the remaining machines were tested, not only at full load, but at an output 20 per cent. in excess of full load.* No. 3 set was run at 55 amperes and 2,200 volts for five hours, and then at normal full load for another hour. No. 2 set was run at 39·5 amperes and 2,000 volts for five hours, and then at 41 amperes and 2,200 volts for an hour. No. 1 set was run at 25 amperes and 2,000 volts for five hours, and then at 27·5 amperes and 2,100 volts for an hour.

Thus No. 1 machine was overloaded by 16 per cent., and Nos. 2 and 3 by about 20 per cent. *All machines ran satisfactorily at these overloads, as well as at their nominal maximum output.* In every

Digitized by Google

case the load was obtained by the use of tubs, so as to be strictly non-inductive. The current was measured on Kelvin ampere gauges and the volts on Ayrton and Mather electrostatic voltmeters, in addition to the switch pillar instruments, and we believe that the measurements so made are, for all practical purposes, completely accurate.

2. Each of the exciters was run, on an external resistance, at full load for about six hours, and gave its full output.

3. The feed pumping engines could not be tested to their full output, as we were unable to get more than enough work for one boiler. The maximum load which we were able to put upon any pump was between 7,500lb. and 8,000lb. of water delivered per hour. Each of the two pumps appeared able to furnish this delivery with ease.

4. *The specified combined efficiency has been on the whole considerably exceeded.* No. 1 gave 76·8 per cent. at full load and 80 per cent. at 17 per cent. overload.† No. 2 gave 80·6 per cent. at full load and 81 per cent. at 20 per cent. overload. Nos. 3 and 4 gave a mean of 81·1 per cent. at full load, and No. 3 gave 83·7 per cent. at 20 per cent. overload. Thus, although No. 1, the smallest set, has fallen very slightly short of the specified efficiency at nominal full load, it exceeded it when overloaded, and the other three sets have very considerably exceeded it, even at their nominal full loads, *and we consider the results obtained in this matter highly satisfactory.*

In order to obtain the fullest information as to the efficiency of the machines, we indicated them not only at full load but also at various smaller loads, as well as when running excited only. The detailed results of these tests are set forth in the tables.

In all these experiments Crosby indicators were used, with tested springs, and the electrical instruments were read, the indicator diagrams taken and the revolutions noted simultaneously, by separate observers.

In the case of No. 1 machine, indicator diagrams were also taken at several different powers while running on the circuit in the evening. In this case the load was one which had considerable self-induction, in consequence of the number of transformers on the circuit, and it was found that the apparent E.H.P. (corresponding to the product of amperes and volts) exceeded the real E.H.P. by about 13·5 per cent. over a range between 35 E.H.P. and 60 E.H.P., the difference between the apparent and real output being, in fact, very nearly a constant percentage over this range. No doubt the difference will tend to diminish as the total load increases, as we believe that many more lamps can be served from each transformer than are at present connected up.

5. The steam consumption of the engines was measured by weighing the water passing away from their surface condensers. In the case of No. 1 set this amounted to 19·7lb. per I.H.P. hour at full load and 20·2lb. per I.H.P. hour at 17 per cent. above full load. For No. 2 set the figures were 20·8lb. per I.H.P. hour at full load and 20·3lb. at 20 per cent. above full load. For No. 3 set the figures were respectively 19·3lb. and 19·6lb., and for No. 4 set the consumption was 19lb. per I.H.P. hour at full load. These figures are a little above those which have been guaranteed, but as the efficiencies of the machines are also above the guarantees, the consumption of steam per *E.H.P. hour*, which is the really important matter, is practically the same as that corresponding to the specification. *We therefore consider the results as to steam consumption to be quite satisfactory.* We made consumption tests at various loads below full power, and the figures for these tests are given in the tables.

6. The measurements of magnetising energy were made by means of the station instruments in the switch pillar, which have been taken as correct for this purpose. A calibration made in the station after the tests showed that their errors were, at any rate, sufficiently small to be negligible. The percentage of magnetising energy to total output are shown in Tables II., III., IV. and V., from which it will be seen that they are (with the exception of No. II.) somewhat larger than the specified ratio of 2½ per cent.

7. *The temperatures of the alternators at the end of six hours' continuous full-power run appeared to be in every case not only well within the specified limits, but quite exceptionally low. The two larger machines were practically cold after their six hours' full-power run.*

8. We regret that we were unable to make any measurement of the insulation resistance of the machine, as the testing set at the station was found to be out of order, but we have no reason to suppose that the insulation was not quite satisfactory.

9. Instead of measuring the fall of potential directly, we measured the excitation at constant speed and constant E.M.F., which gives the same proportionate result, and is more readily determined. The results are given in Table VI., and show that the variation differs greatly from 7½ per cent. (which corresponds to 150 volts in 2,000) in the different machines. In Nos. 1 and 4 it averages about 12 per cent., in Nos. 2 and 3 about 3·6 per cent. It is to be noted, however, that we could only measure the excitation at the terminals of the field resistances, and not at the terminals of the field windings themselves. This probably accounts for the obvious discrepancy of these figures. Within reasonable limits of variation, however, it does not appear to us that the constancy of excitation is a matter of any practical importance.

† In this case the machine was driving its own exciter, and the exciting watts are added to those of the alternator in computing the output and efficiency.

Table VI.—*Variation of Excitation between half and full load.*

Set.	Exciting energy (kilowatts).		Variation per cent.
	Half load.	Full load.	
1	1·38	1·58	12·6
2	1·39	1·44	3·47
3	2·57	2·67	3·75
4	2·42	2·74	11·7

10. The full power runs of the main engines have already been mentioned. The engines, as well as the alternators, ran well; but it appeared to us that the consumption of lubricating material was somewhat unusually large. It may well be that this matter will rectify itself when the engines have run somewhat longer.

No difficulty was found in running the exciters in parallel. *Alternators Nos. 1, 3 and 4 were run in parallel at different loads in accordance with the terms of the specification, and ran in general satisfactorily.*

11. The circulating and feed-pumping engines were run for much more than the specified period of six hours at as great a load as the conditions of station working allowed us to put on them. The feed pumps ran without the least trouble. The circulating pump engine did not run so satisfactorily; it seemed to be somewhat too small for its work.

We observe that in Nos. 3 and 4 machines a metallic shield has been inserted as a protection of the field winding from the armature coils. *This is a very important improvement in the design of the alternators.*

On the whole matter of the running plant in the station, it gives us pleasure to say generally, in conclusion, that *as to output, efficiency, and economy, as well as in respect to general construction, the results are very satisfactory*, and are substantially in accordance with the conditions of the specification.

STORAGE BATTERY MANIPULATION AT THE BOSTON EDISON STATION*.

How valuable an auxiliary the storage battery may be in central station service has long been recognised in European practice, and the recent success of its application by the Boston Edison Illuminating Company demonstrates that the conditions in this country

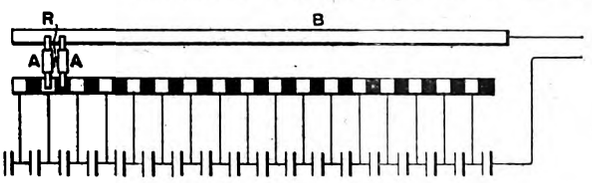

FIG. 1.—Working Circuit.

are no less favourable as to its utilisation in that service. As attention has now been generally directed to the subject, and as the application of electrical storage is likely soon to be widely extended, the method of switchboard manipulation of central station batteries has become a matter of interest.

The switchboards of the Boston Edison Company appear at first sight complicated, but in reality the electro-mechanical devices included are of the simplest nature, though displaying considerable ingenuity in their automatic action. Taking the case of the more recent switchboard, it controls a plant of 144 cells, 72 being on either side of the neutral wire. As the voltage demanded varies it is necessary to switch in more or less cells, and it is also necessary to vary the number in circuit when charging. The switchboard has for its aim the accomplishment of this regulation. The contacts must be very substantial, and therefore do not move easily. The contact shoe must not slip from one plate before it has made contact with the next. To operate a set of sliding contacts of this nature by hand would be impracticable, and hence the automatic devices.

The elementary design of the working circuit is shown in Fig 1. B is the positive bar and feeds the plus mains, while the minus mains find a terminal at the batteries. A A are travellers operated by a mechanism, and cut out more or less cells. The two travellers

* Abstract from the *Electrical World*, of New York.

Digitized by Google

are connected by a German silver resistance, R, so that if they bridge two contacts they will not short-circuit the cell, the resistance burning out. The method of moving these travellers along the bars is electro-mechanical, and it is here that the ingenuity of the designer is called into play. This particular board moves its travellers by a reciprocating rack in which pawls on the traveller engage. The rack is reciprocated by an electric motor, which turns, by means of a worm wheel, a gear actuating a crank and connecting rod motion.

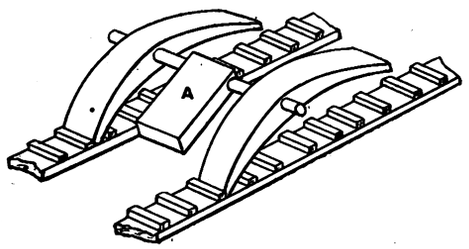

FIG. 2.—Twin Pawl.

A sketch of the double pawl is shown in Fig. 2. There are two crank plates on the axis of the gear wheel, and each of these reciprocates a rack in exact unison, and in the same phase. The iron piece A, rigidly fastened to the pawl axis, is placed between two magnets, one of which can lower and the other can raise it. By this means the pawls are tilted in either one or the other direction and engage with the rack or its journal, or return stroke, according to circumstances. Thus the traveller is drawn along by the rack, and in a single stroke of the latter one cell is cut out. The pawl

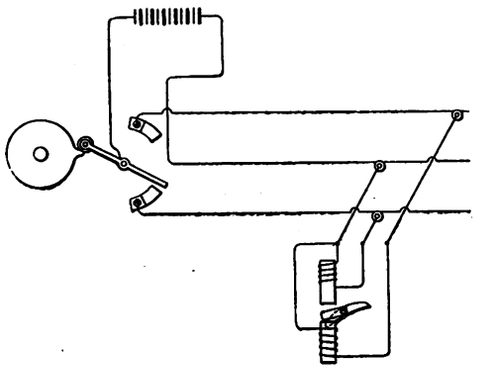

FIG. 3.—Connections of Switch and Pawl Magnets.

magnets receive their current from a system of three little trolley wires. Of course, only one magnet is excited, and according to the direction it is desired to move the traveller. Therefore, the middle trolley wire only is permanently charged, and that is common to both magnets. The other terminals of the magnets go to the upper and lower trolley wires respectively. A switch thrown by a cam on the crank plate completes the circuit through the upper or lower trolley wire, as the case may be.

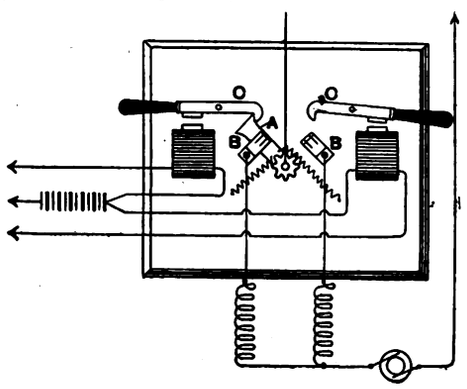

FIG. 4.—Arrangement of Switch.

Fig. 3 shows the connections. The magnets operate at a potential of 12 volts from a circuit around six storage cells. The motors that reciprocate the rack are series motors, and have two field coils, one of which will turn the armature in one direction, and the other in the reverse direction. A single-pole two-point switch is sufficient to reverse the motors. The connections of the latter are shown in Fig. 4. A is a single-pole double-throw switch of special construction. Springs normally maintain it in a vertical position. When turned to the right or left it starts the motor in one or the other direction, as shown by the connections. The latch, C, holds the switch in position, and the motor in turning over its gear wheel cuts the releasing magnet into the 12-volt circuit, and the switch flies back, opening the motor circuit and stopping the mechanism after it has advanced one cell. The levers latching the motor switch also have handles, so that they may be operated by hand in case the releasing magnets should not act. If more than one cell is desired to be cut in or out, it becomes necessary to hold the motor switch until the first click of the releasing gear has taken place, and it will then be held to be released on the second revolution of the crank plate. The motor axles are prolonged beyond their bearings, and are milled square to admit of a crank being placed thereon, in order to operate the traveller, should the motor become disabled.

Of the three wires coming from the cut-out magnets, the middle one passes to the cells, and, emerging from them six cells away from where it entered, passes with the other two terminals to three little brushes hanging over the cylindrical surface of the crank plate. Two insulated pieces of metal are placed on opposite sides of the circumference and connect the middle brush with either side brush in turn. Thus a single release magnet is operated, and then the other, alternately. It remains to be stated that the apparatus is beautifully simple and works with great smoothness and precision, completely controlling the number of cells in circuit.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, January 17th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "More about Argon," by the Right Hon. Lord Rayleigh, F.R.S.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

7:30 p.m. Fourth General Meeting in the Lecture Hall of the Literary and Philosophical Society of Newcastle-on-Tyne. Discussions on the following Papers: (1) "On the Surface Condensing Plant at the Newcastle and District Company's Electric Light Works, Forth Banks, Newcastle-on-Tyne," by W. Cross; (2) "An Investigation into the Forces Tending to Produce Vibration in High-Speed Engines," by J. M. Allan.

MONDAY, January 20th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture I.: "Alternate-Current Transformers," by Dr. J. A. Fleming, F.R.S.

TUESDAY, January 21st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The Sanitary Works of Buenos Ayres: Sewage, Drainage and Water Supply," by the Hon. R. C. Parsons.

WEDNESDAY, January 22nd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Supply of Sea Water to London," by Frank W. Grierson.

THURSDAY, January 23rd.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting.

FRIDAY, January 24th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read: (1) Exhibition of Some Geometrical Instruments," by E. Scott and Signor Monticolo; (2) "On Resultant Tones," by J. D. Everett; (3) "Experiments with Incandescent Lamps," by Sir David Salomons.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Ludwig and Vitalism" by Prof. Burdon Sanderson, F.R.S.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Toynbee Hall.—The philanthropic work of this institution in the East End of London continues to be of the same useful and practical character as hitherto. For the ensuing session, classes and practical instruction in various scientific and other subjects have been arranged.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[In preparation.*

NOTICE.

With the current number of "The Electrician" is issued as a Supplement (Gratis) a fine Steel-Plate Portrait of Dr. JOHN HOPKINSON, President of the Institution of Electrical Engineers. Complaints of non-receipt should be at once sent to the publisher.

FROM THE CONSUMER'S POINT OF VIEW.

IT is somewhat fortunate both for the Electrical Industry and the British Public that the awe-inspiring discussions as to the exact "current that kills" which crop up from time to time in the electrical and medical journals are beyond the ken of the "average man." The great British Public does not affect electrical and medical literature of the solid order; and if it did, quite 96 per cent. would be more or less unintelligible. It is only when the Edisonian oracle across the Atlantic speaks to us in its well-worn sensational style, or when some unusually gruesome accident occurs to an unfortunate employee, that the general public is troubled by visions of unknown dangers lurking behind the simplest application of electrical energy. Dr. HEDLEY, in a recent number of the *Lancet*, quite soberly and quite rightly draws attention of the medical profession to the undesirably high voltages to which a patient undergoing electrotherapeutic treatment in a bath may be exposed, provided certain simple precautions are not taken, if the current be supplied from the mains of a company with an earthed system. Again, in our last issue, Mr. ALBION T. SNELL described a certain "vile concatenation" of untoward circumstances, which would result in a consumer getting the full pressure between the outers of a three-wire system into his house. It is also thought by some that in admitting a 250-volt current into consumers' houses at all the safety limit has been passed in regard both to life and fire. As regards life, the impossibility of procuring a supply of willing experimental objects, and the difficulty of making accurate measurements even if the supply were forthcoming, added to the widely-varying conditions which obtain in the involuntary experiments made at long intervals, place the expert and the ignoramus much on a level in this matter, and nothing more than a rough approximation to the truth, derived from a much longer experience than we have had as yet, need ever be expected. As regards fire, it would

Digitized by Google

be comparatively easy to reproduce with sufficient accuracy the conditions likely to occur in actual practice, and to test by actual trial the behaviour of good, bad, and average wiring under 250 volts as compared with 100 volts. The sooner this is done the better. But dismissing for the moment such grave considerations as the danger to life and the danger from fire, let us try to look at the 250-volt question, and other questions of a similar nature, from the consumer's point of view.

Unless some serious catastrophe occurs to awaken his fears—an eventuality which need not be apprehended—the danger aspect of the matter is not likely to assume prominence in the mind of the consumer. Nevertheless, the introduction of 250 volts into consumer's houses will touch him at many points, and these may prove sore points. If he has to part with his cherished and very useful 8 c.p. lamp, he will scarcely regard the latest step in the march of electrical progress with favour. Fuses, of course, need not be expected to "go" daily in an ordinary well-managed household, but if, when they *do* go (accidents, we know, will happen, even in the best regulated families), they go off with the report of a pistol, the householder may very possibly get nervous. Again, if his lamps also acquire the habit of breaking frequently and at the most awkward moments, it is just possible the consumer may fall into that dangerous frame of mind in which he begins to wonder whether the "new illuminant" is worth all the bother it entails. When in this unjudicial mood it may be doubted whether he will differentiate even with approximate accuracy between the rapid dimming and frequent breakages due to the endeavour to supply the market prematurely with 250-volt lamps, and those due to the advent of cheap and nasty 110-volt lamps; a plague on both your causes, will be his irreverent exclamation. The parallel running of alternators is also a subject of transcending interest to engineers and mathematicians. To the consumer the interest of the game mainly centres on the occasional wild throbbing of the light when two self-willed machines are ordered to get into phase, or on the momentary, but nevertheless alarming, blink noticeable on circuits where the obstinacy of the alternator—or of the engineer—prevents even an attemp at paralleling. *Per contra*, the alternate-current systems are under no necessity to supply the consumer with high-volt lamps, since these may work their feeders at voltages of any degree, while still retaining the 100-volt lamp, which no other system can do without the aid of intermediate moving machinery. Again, a goodly proportion of house fittings, notwithstanding fire-office rules and supply company rules, are at present a source of mild electric shocks. Now it is open to question whether the epithet of mild will be applicable to the language of the *pater familias* who receives the "full force" of 250 volts; at any rate we feel sure the recipient of the shock will not consider it as twice blessed, and bless the company that gave it him, as well as his own good fortune in receiving it. Ultimately, of course, equilibrium will be established. High-pressure steam has given us better boilers, high-pressure current may reasonably be expected to give us better wiring, and possibly a reduced tariff. We trust, however, that the every-day convenience of the consumer will not be entirely overlooked. If it is, he will not fail to do as he is done by.

So much for the matter of the pressure of supply from the consumer's standpoint. On the subject of house wiring no doubt he also has his opinions, inarticulate at present, probably illogical, but possibly worthy of some consideration. To our mind, one of the many merits of iron-barrel and of concentric wiring is that they are calculated to remind the consumer of the familiar gas pipe. The external resemblance between the early railway carriage and the old stage coach induced many a timid conservative to adopt the new mode of locomotion, and if the householder finds that, in lieu of a maze of mysterious-looking wires in ugly wooden troughs, something bearing a striking resemblance to his old familiar friend the gas pipe is all that an installation of the electric light need involve, he may come to regard the adoption of the new mode of illumination less as a bold departure and more as an inevitable matter of course. Apart from the aforesaid graver considerations of safety, the average householder will probably consider the best form of wiring to be that which looks simple, costs little and gives the least trouble. He, at any rate, poor man, does not wish to be for ever drawing wires in or drawing wires out. Once he has paid his bill for the job, he will be inclined to measure the efficiency of his wiring system in much the same way as he measures the efficiency of his digestive system: he will be content to ignore its existence.

REVIEW.

Gleanings from Patent Laws of all Countries. By W. Lloyd Wise, J.P., F.R.G.S. (Cassell and Co., Limited.)

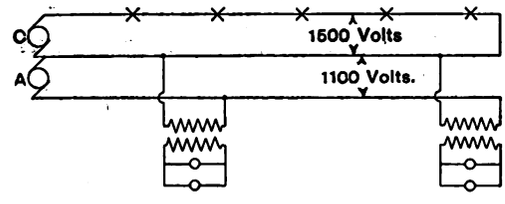
Works on patent law are so frequently either of such a highly legal nature, or deal with the subject in such an elementary fashion, that, as works of reference, they are of little or no value to owners of patents and inventors, requiring, in the one case, a much greater expenditure of time to peruse than is usually at the disposal of business men, and in the other affording but little definite information on points of practical interest.

The first portion of the work we have before us, which deals in alphabetical order with the patent laws of twenty-two countries (ranging from Argentine Republic to Germany), is not open to these objections, for, whilst giving precise particulars as to patent law *and practice* in the several countries, the headings under which these particulars are classified are such as to enable the information with regard to any special point to be readily turned up and digested. The headings include "Who may obtain a Patent," "Subject Matter," "Application, Procedure, Grant," "Term," "Fees (Government)" and "Assignment and Transfer of Patents."

The notes as to the productions, industries, &c., of each country, will no doubt be useful to persons interested in inventions and patents.

AN ECCENTRIC SYSTEM OF ELECTRIC SUPPLY.

Doubt having been expressed as to the possibility of working continuous and alternating currents on the same system of conductors, a writer has sent to the *Electrical World* of New York a description of an instance of this combination having been actually effected. The connections between the two generators, which were a Brush arc machine, C, and a "National" alternator, A, were made as is shown in the following diagram:—



This experiment was made about three years ago, on a three-wire supply system at Brunswick, Me. The pressure of the continuous current was 1,500 volts, for running arcs in series; and the pressure of the alternating current was 1,100 volts, for distribution to transformers in parallel. The experiment was tried under severe conditions, but, it is said, both sets of lights and both machines ran smoothly. It is admitted by the writer that there is some risk of the current from one machine running through the armature of the other.

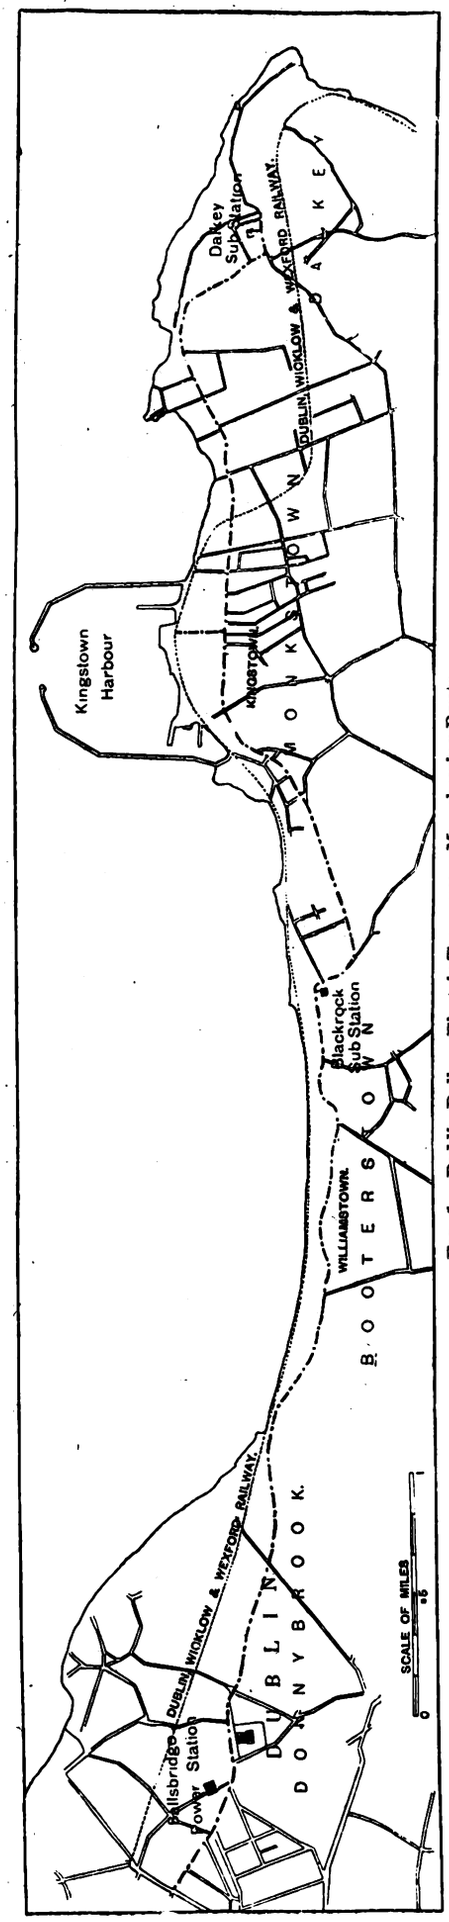

FIG. 1.—Dublin-Dalkey Electric Tramway. Map showing Route.
——·——·—— Electric Tramway. ..... Dublin, Wicklow and Wexford Railway (steam).

THE DUBLIN-DALKEY ELECTRIC TRAMWAY.

The conversion of the original horse tramway between Dublin and Dalkey into an electric line having now been practically completed, and successful trial runs of cars over a portion of the line having already taken place, the interesting event of the inauguration of this line may be expected shortly to occur. The line is owned by the Southern District Tramways Company, of Dublin, the Managing Director of which Company is Mr. George White, whose name has already appeared in these columns in connection with the recently-opened electric line of the Bristol Tramways Company, of which he is also the Managing Director. The extent of the Dublin-Dalkey Electric Tramway is shown by the accompanying map (Fig. 1), and it will be seen that, starting from Dublin at a point about half a mile north of Balls Bridge, where the generating station is situated, the line passes through Donnybrook, Williamstown, Blackrock, Kingstown—where a branch traverses streets leading to the harbour—and thence to Dalkey. Throughout the greater part of its main route the tramway is roughly parallel with the Dublin, Wicklow and Wexford steam railway.

Acting upon the advice of their consulting engineer, Mr. J. Clifton Robinson, the Tramway Company gave the contract for the electrical equipment of the line, the reconstruction of the track and of the buildings for the power-station and substations, and the erection of the generating plant, &c., to the British

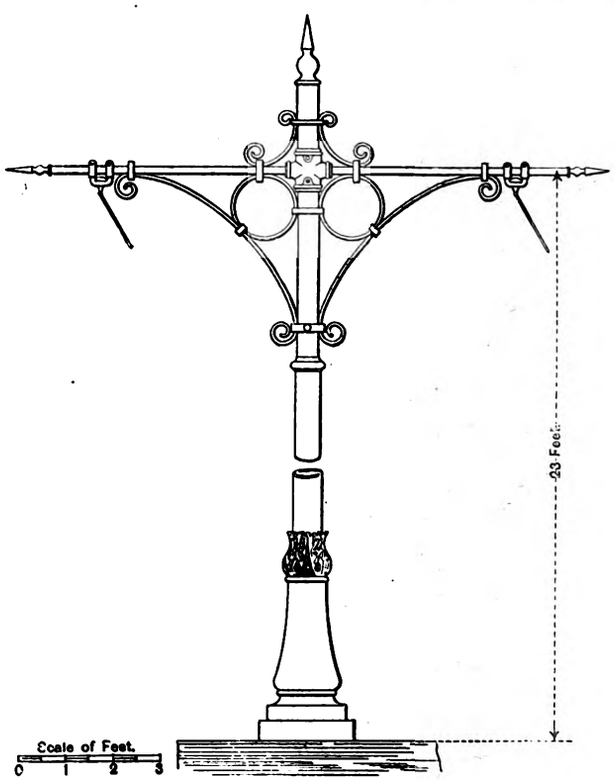

FIG. 2.—Dublin-Dalkey Electric Tramway.
Pattern of Pole used for Bracket Supports in centre of Track.

Thomson-Houston Company, by whom sub-contracts were given to Alderman Meade, of Dublin, for the building construction, to Messrs. Kellners, of London, and Mr. A. Krauss, of Bristol, for the reconstruction of the track, and to Messrs. Callender's Bitumen, Telegraph and Waterproof Company and the British Insulated Wire Company, for cables. The contracts were carried out under the supervision of Mr. A. J. Ireland (chief engineer) and Mr. C. W. G. Little (resident engineer) on behalf of the chief contracting company. The portion of the line between Kingstown and Dalkey was commenced near the end of 1894, and the other portion, extending towards Dublin, early in 1895. Some opposition was at first raised by the ratepayers of Dalkey; but, after a deputation had been received, the matter was satisfactorily cleared up, and the work of construction proceeded.

The track, which is $7\frac{3}{4}$ miles in length, is on the whole fairly level, the principal gradients being 1 in 16, 1 in 23, and 1 in 29. It is double throughout, except for a short distance in two places. The guage is 5ft. $2\frac{3}{16}$in., and the rails, which are of 76lb. size, with massive fish-plates, are laid in concrete. The electrical equipment of the track is upon the overhead trolley system, span wires being principally used, with centre poles in some of the narrower streets, and along the chief road through which the Kingstown branch passes. The style of the centre poles is shown in Fig. 2, from which it will be seen that these are far from

Digitized by Google

being inartistic. Indeed, the appearance of the centre poles with double brackets is undoubtedly superior to that of the plainer side poles, with their numerous span wires crossing the streets at right angles. The return current is through the rails, which are bonded on the Chicago plan, single bonding being used throughout, with cross connections at every 120ft. The trolley wires, which are duplicated throughout, are of hard-drawn copper, 320 mils in diameter. The poles, whether for the central or side

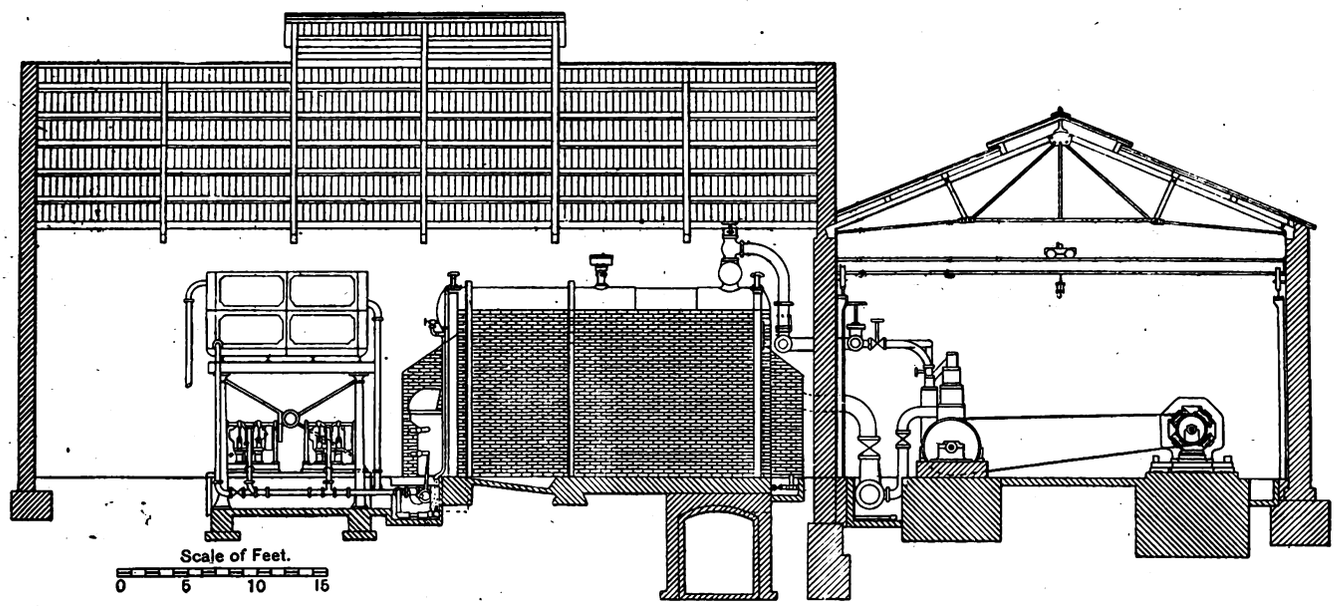

FIG. 3.—Dublin-Dalkey Electric Tramway. Longitudinal Section of the Generating Station.

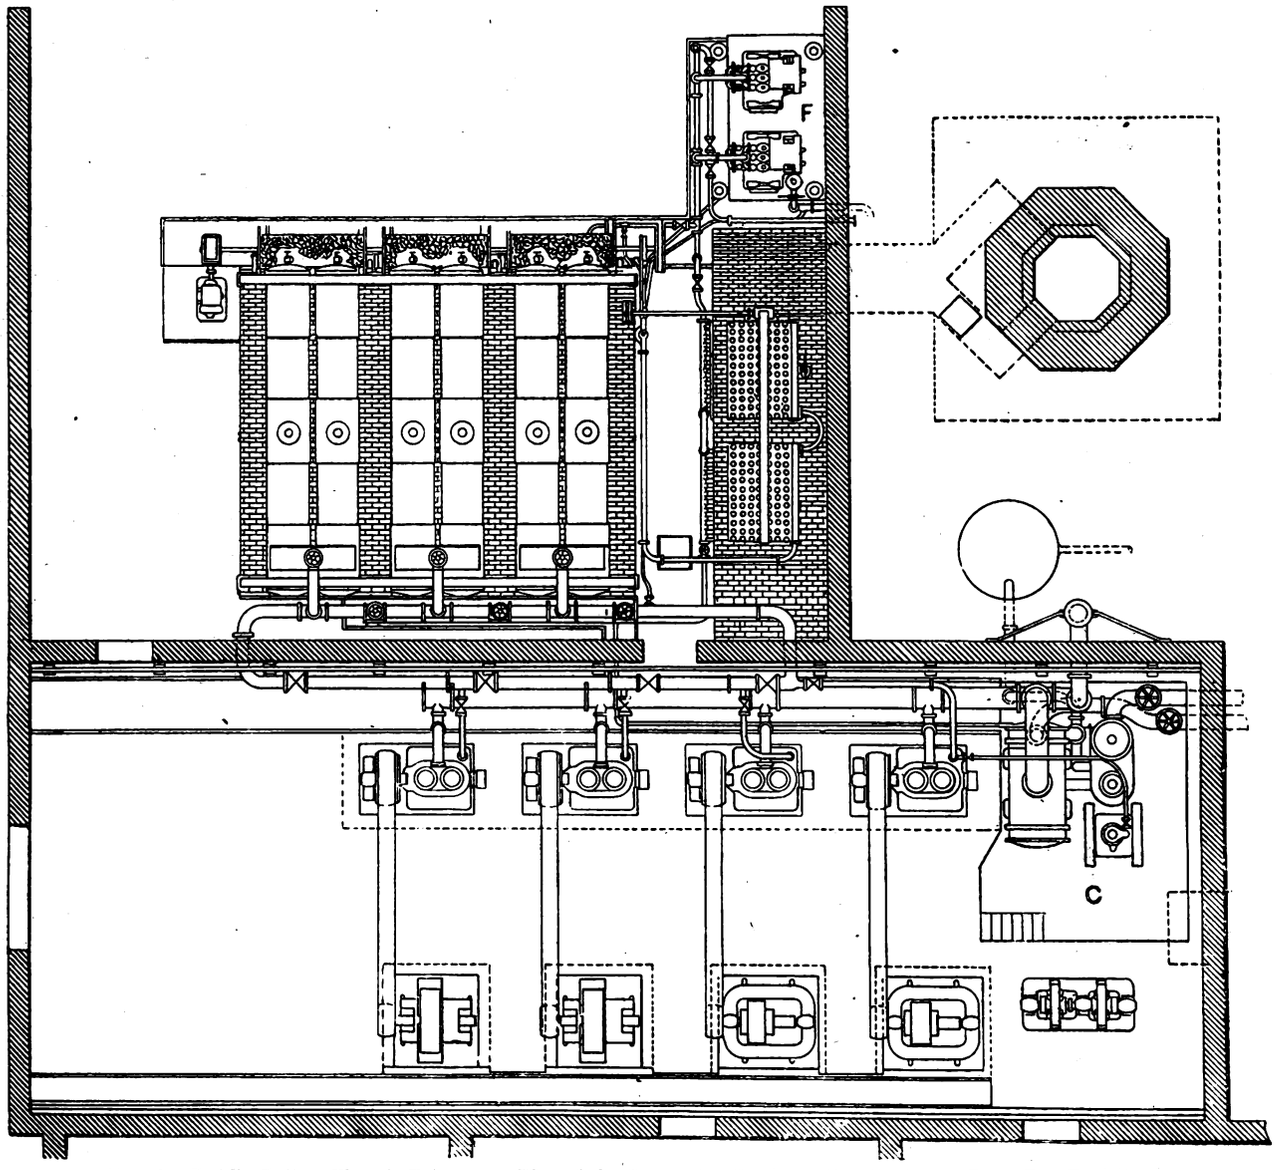

FIG. 4.—Dublin-Dalkey Electric Tramway. Plan of the Generating Station. C = Condenser Pit. F = Feed Pumps.

Digitized by Google

construction, are of steel tubes in three sections, with hot-shrunk over-lapping joints. They are grounded to a depth of 6ft. in concrete, a cast-iron base and foot-plate being fitted over the lower end of the pole. In excavating for the pole groundings considerable trouble was occasionally met with, owing to the rocky nature of the foundation; and the pits had in some places to be blasted out. The span wires are of mild-steel cable, $\frac{3}{8}$in. in diameter; they are fastened to the side poles by means of insulated buckles, which are secured to wrought-iron strips, these being clipped around the poles. From the span wires—or from the brackets, where central poles are used—the trolley wires are suspended in the usual manner, by insulators; and, of course, every half-mile is capable of being isolated from the system. At the ends of each half-mile section, section insulators are used; and here the ends are connected to rubber-covered cables leading down the poles to the switch pillar, in which there are switches by which the sections may be connected to the continuous-current feeders. These switch pillars are erected along the route, beside the vehicular way; they are of cast iron, and in general appearance resemble postal pillar boxes, except that they are of a more ornate design. They are 4ft. in height and 18in. in diameter.

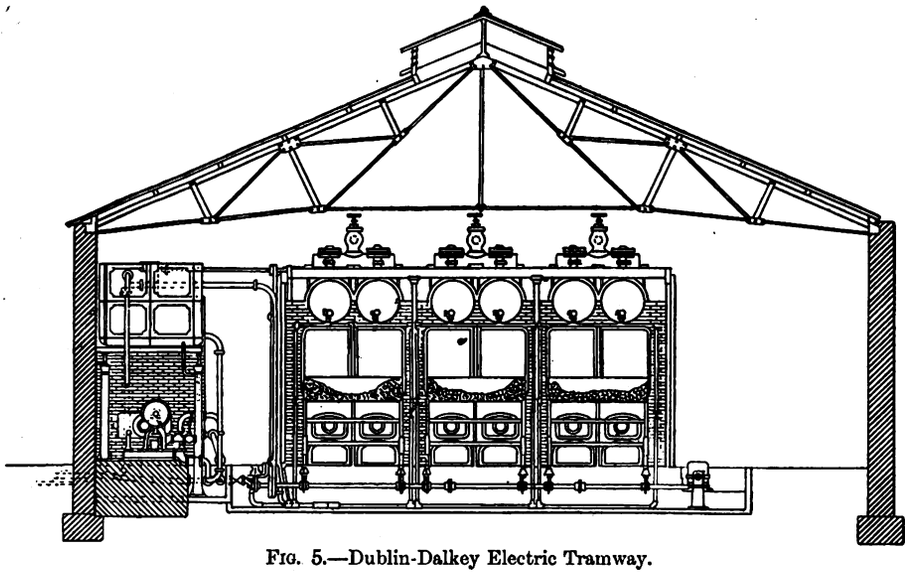

FIG. 5.—Dublin-Dalkey Electric Tramway.

Transverse Section of Boiler House, showing boiler fronts, feed tank, electric pumps, and electrically-driven automatic stokers.

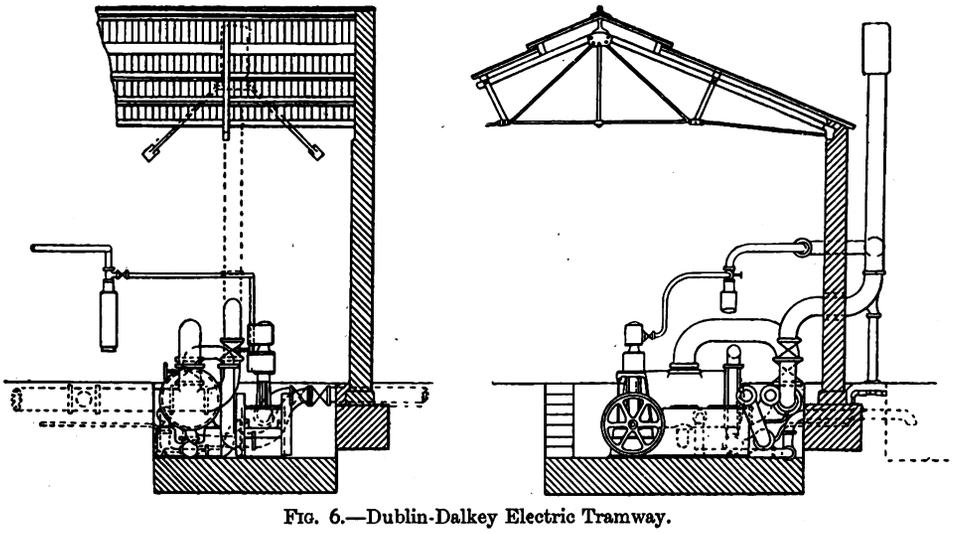

FIG. 6.—Dublin-Dalkey Electric Tramway.

Longitudinal and transverse sections of the Condenser Pit, showing Surface Condensing Plant.

One of the most interesting features of the Dublin-Dalkey tramway system consists in the adoption of power transmission by means of polyphase currents, between the power house and the two sub-stations which feed the line *en route*. A glance at the map will show that the position of the power station would render it difficult to comply with the Board of Trade regulation in regard to the drop of pressure on the return circuit through the rails, except by means of sub-stations at the far end and an intermediate point on the line. This regulation insists that the fall of pressure on the entire length of the return circuit shall not exceed 7 volts. It was therefore considered desirable to adopt polyphase transmission between the power station and the two sub-stations, the one at Dalkey and the other at Blackrock. The sites for the main and secondary stations were fixed by the existence of car sheds and stables, belonging to the original horse tramway system, at these places; and the old buildings on these sites have been partially utilised and reconstructed to suit their present purpose.

The power house is situated on the banks of the River Dodder, which provides water for condensing purposes. The equipment of the power house provides plant for directly feeding the nearer end of the line with continuous current at 500 volts; as well as for transmitting three-phase power, at from 2,300 to 2,500 volts, to the distant sub-stations. The arrangement of the station equipment is shown in Figs. 3 to 6. Figs. 3 and 4 show, on the same scale, a longitudinal section and a plan of the station; Fig. 5 is a transverse section of the boiler house; and Fig. 6 shows a longitudinal and a transverse section of the condenser pit, which is shown in plan at C, in Fig. 4, all these illustrations being on the same scale.

In the boiler house there are some interesting features. There are three Babcock-Wilcox boilers, each provided with double steam drums, of 250 H.P. per boiler. These develop a normal pressure of 140lb. on the gauge. The boilers are fired mechanically, by means of Vicars stokers; and the gear for these stokers is driven by a G.E. shunt motor, which also drives the scrapers in the Green's economiser. The feed water is supplied either by means of an injector, or by two three-throw pumps, made by Messrs. Daniel Thompson and Co., each of which is driven by a G.E. motor, of the same type as those used on the cars, but shunt wound. Fig. 7 shows a longitudinal and transverse elevation of one of these electrically-driven feed pumps. All the motors in the boiler house are worked from the 'bus bars, at 500 volts, through special rheostats and switchboard. The feed pumps are capable of supplying 16,000lb. of water per hour. The feed water is taken from a large storage tank, or from the town supply direct, or from the hot well of the surface condenser, and is passed through a Green's economiser consisting of 192 pipes. An octagonal brick chimney, 111ft. 8in. in height and 6ft. diameter at the top, carries off the furnace gases after they have passed through the economiser flues.

A ring main steam range, shown in Fig. 4, collects the steam from the three boilers, single branch pipes being T'd to each of the boilers as well as to each engine. The main ring is 8in. diameter, of mild steel; the T-pieces and bends are of cast steel; and the branch pipes to the engines are of copper, $4\frac{1}{2}$in. diameter. The stop valves in the main ring and at each branch are of the Hopkinson pattern; they are arranged so that any defective section of the plant can be shut down without interfering with the working of the rest.

In the machinery room there are at present four generating sets, each driven by a 150 B.H.P. Willans (H.H.S.) compound, condensing, two-crank engine, running at 380 revolutions per minute, with steam at 140lb. The engines have been specially strengthened to stand the severe loads which traction work temporarily imposes, and will develop 175 B.H.P. for a short time on occasion. The engines are adapted to belt driving,

Digitized by Google

each being provided with a 3ft. 10in. flywheel pulley, and with an outer bearing. Two of the engines drive two "B.T.H." 100-kilowatt four-pole tramway generators at 625 revolutions per minute. These are compound wound for 500 volts at no load and 550 volts at full load. The other two engines are belt coupled to two eight-pole three-phase generators, each capable of developing 120 kilowatts at from 2,300 to 2,500 volts, running at 600 revolutions per minute. These machines were designed by Mr. H. F. Parshall, and were manufactured at Newcastle-on-Tyne by Messrs. Armstrong, Mitchell and Co. In addition to these four generating sets, there is a "B.T.H." four-pole motor generator of 30 kilowatts capacity, consisting of a 500-volt shunt motor direct coupled to a 125 to 140-volt continuous-current generator, for supplying the station lights and charging the storage batteries. This motor-generator is situated at one corner of the machinery room in line with the dynamos, as shown in Fig. 4.

Surface condensing plant is provided in a pit sunk below the level of the machinery room, and the steam plant may be run either condensing or non-condensing. The condenser pumps are driven by a separate small steam engine. The capacity of the condenser is rated at 19,000lb. of steam per hour.

The switchboards are arranged on the panel system, a separate panel being provided for each machine. Those for the 100-kilowatt 500-volt generators are the standard British Thomson-Houston form of K panel, consisting of enamelled slate slabs measuring 19in. by 24in. wide, each carrying an automatic circuit breaker with magnetic blow out, one 300-ampere illuminated dial Weston ammeter, one field rheostat with switch connected to special resistance to take the discharge current on opening the field circuit, one pilot lamp, one voltmeter, single-pole switches, one lightning arrester and Thomson recording wattmeter. There is also a single-pole switch for the series lighting circuits. The 'bus bars and all connections are carried at the back of the board, the positive bus bar is connected to the 500-volt trolley wire-feeder, and the negative 'bus bar to the rails forming the return circuit. The dynamo and 'bus-bar voltmeters, which are the Weston type, are mounted on a bracket, which projects from the end of the switchboard. The equalising switches are mounted on separate pillars, close to the generators. For the three phase plant four separate panels are provided, two being for the generators and two for the feeders, the former each carrying a three-pole high-pressure switch of special design, three high-pressure fuses of the Ferranti oil brake type, three ammeters and one voltmeter, field rheostat, and synchronising gear. The feeder panels each carry a three-pole high-pressure switch and an ammeter. The three-phase generator fields are excited from the 500-volt 'bus bars. The above panels which constitute the main switchboard are bolted to vertical iron supports, there being about 3ft. space between the wall and the back of the board. In addition to the above there are two separate panels, one for controlling the high-pressure side of the motor-generator and the station motor circuits; the other carries the switch gear for the low-pressure side of the motor-generator, the accumulators and the station lighting circuits. This board is so arranged that the secondary side of the motor-generator may be run as a motor when connected to the accumulators, so as to give 500 volts on the high-pressure side for operating the station motors when the main plant is standing idle. This small switchboard is placed beside the motor-generator at one end of the engine room. The cables between the dynamos and switchboard consist of class L rubber-covered cables, laid in trenches and supported by porcelain insulators. The accumulators are of the Epstein type, there being 55 cells of the R 11 pattern having a capacity of 600 ampere-hours.

The repair shops are fitted with a complete set of machine tools, consisting of lathe, shaping machine, drill press, hydraulic press, grindstone, blacksmiths' forge, &c., and a full equipment of small tools. The machine tools are driven by belt from a countershaft operated by a "G.E." shunt-wound motor run off the 500-volt circuit. The testing room contains the usual testing instruments, a battery of 50 small accumulators, and a portable Silvertown set.

The present rolling stock comprises 20 motor cars, each double-decked and capable of seating 24 passengers inside and 30 on top, the length inside being 16ft. 6in., and over platforms 27ft. 2in. These cars were constructed by Messrs. G. T. Milnes and Co., of Birkenhead, and are of handsome design. They are each lighted by means of five 16 c.p. lamps in series from the trolley circuit. Each car is equipped with two "G.E." tramway motors and series-parallel controllers. The trolley is of the usual American pattern, mounted on a cast-iron pedestal 6ft. 6in. in height. This pedestal is bolted to a stout plank running the whole length of the car roof, somewhat on one side of the centre. In addition to the motor cars there are 20 trailers, similar in general design to the motor cars, but without other electrical equipment than the electric bells and glow lamps. Five extra motor cars and 10 extra trailers are being built.

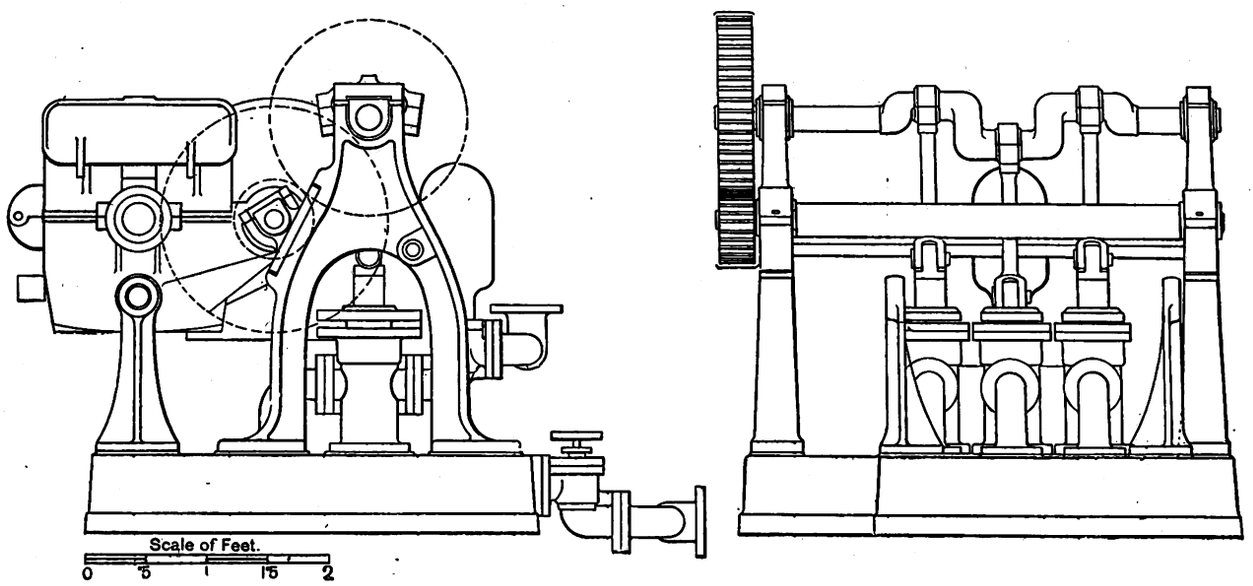

FIG. 7.— Dublin-Dalkey Electric Tramway. Electrically-driven Feed Pump in the Boiler House.

Spacious car sheds have been erected adjoining the power house, and sheds of smaller capacity at the two sub-stations. The position of the sheds at the main station would be represented immediately contiguous to and beneath the plan shown in Fig. 4. There is space for 38 cars in these sheds, arranged on 11 tracks, four of which are provided with pits to enable the cars to be repaired or cleaned from underneath. A traversing table allows of the cars being transferred from any one track to any other. Adjoining the sheds are the repairing shops, the equipment of which has been described above.

At the Blackrock sub-station the plant consists of two direct-coupled units, each consisting of a synchronising motor coupled

Digitized by Google

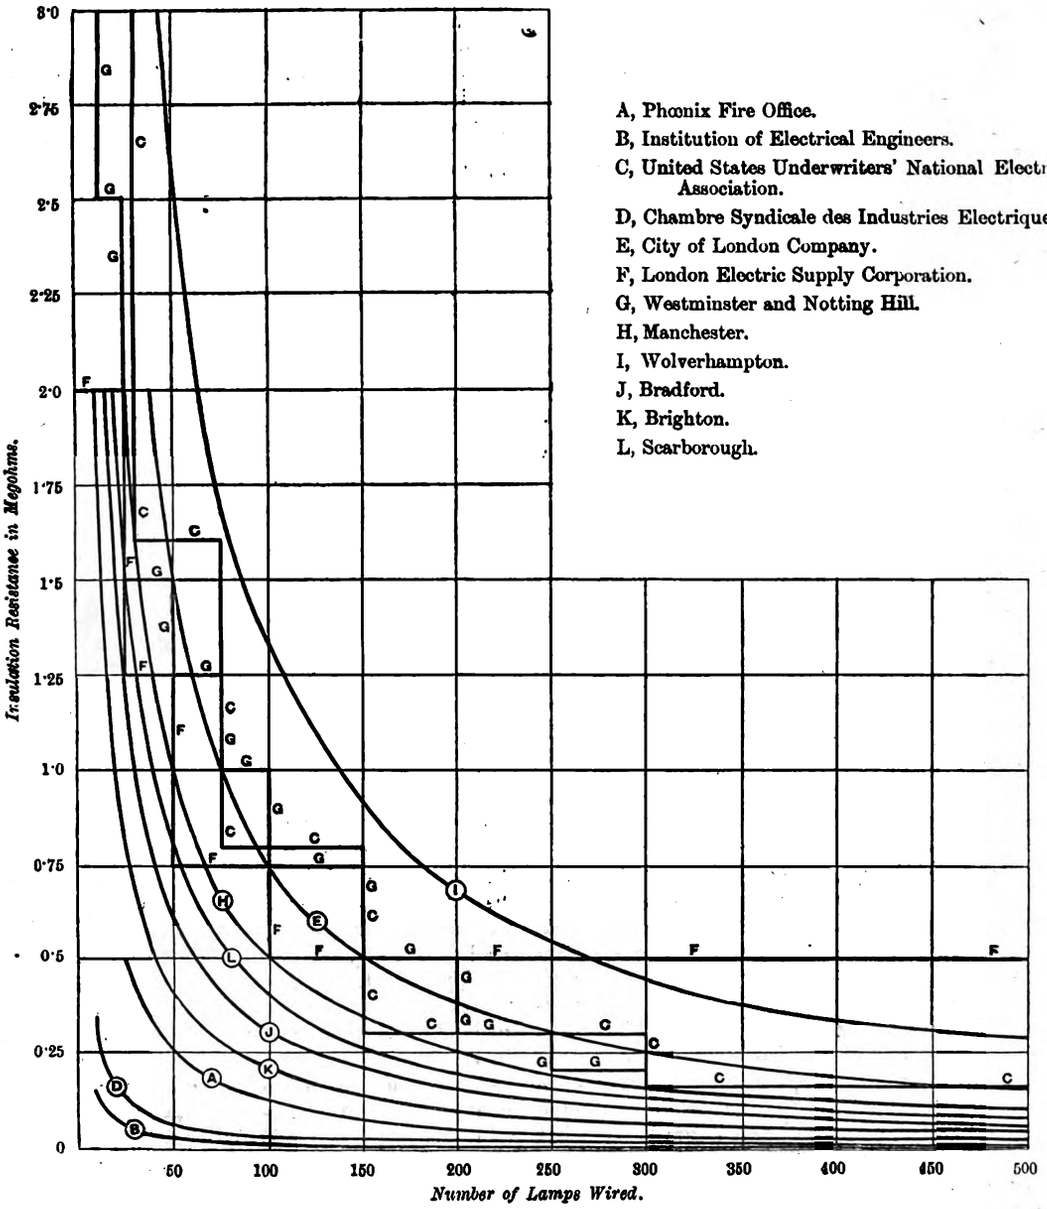
to a 60-kilowatt continuous-current generator. The motor receives the three-phase current at about 2,300 volts pressure, and the generator produces current at a pressure of 500 to 550 volts. Suitable switching gear is provided to enable the generator to be started from the trolley wire feeder to run the motor before throwing it into circuit. There is also a set of switching gear for controlling the direct-current generator, and connecting it to the 500-volt trolley wire feeder. The plant at the Bullock Hill sub-station, at Dalkey, is similar, except that the generators have a capacity of 50 kilowatts each.

Current is carried from the power house by two sets of feeders, one being for the 500-volt direct current and the other for the 2,500-volt three-phase system. The 500-volt feeders, which supply current to the overhead trolley wire, consist of Callender's lead-sheathed armour cables of 0·08 sq. in. and 0·15 sq. in. section. The former cable extends from the power station as far as Blackrock sub-station, but the latter, of course, extends to the Bullock Hill sub-station. The three-phase current is carried from the power station as far as Blackrock sub-station by two triple concentric cables, each of 0·0496 sq. in. section, and from thence to the Bullock Hill sub-station by one triple concentric cable of the same section. These concentric cables are of the British Insulated Wire Company's lead-sheathed and armoured type. In addition to these feeders there is a three-core Callender lead-sheathed and armoured cable, one conductor of which is used as the test wire. The other two conductors are for the telephone system. This cable is led into the feeder switch pillar, and connected to telephone instruments placed at every half mile along the line, and is also carried into the power house and sub-stations, where telephone instruments are fixed.

Our thanks are due to the British Thomson-Houston Company, the contractors, for their kindness in readily supplying us with particulars from which to prepare the foregoing description and illustrations of the Dublin-Dalkey electric tramway.

HOUSE WIRING INSULATION CURVES.

The curves in the accompanying diagram have been drawn upon the basis of the most recently published rules in regard to the insulation resistance of house wiring, which have been issued by the insurance and supply companies and other important bodies. In many respects these rules are the same as those issued on former occasions, but also in many respects they differ from these in important details. We published a similar set of curves in *The Electrician*, Vol. XXXII., p. 265; but since that occasion many of the supply companies have remodelled their regulations in this matter. In the twelve curves selected typical regulations of some of the most important authorities are shown, and many of these represent the rules not only of the authorities whose names are appended, but also of minor provincial supply companies.



Two classes of regulation are apparent in these curves: (1) those which are represented by a regular hyperbolic curve,

Digitized by Google

(2) those which are represented by irregular "stepped" curves. Examples of the former class are shown by index letters included in small circles; examples of the latter by index letters at intervals along the line of the curves, but not included in circles. It should be added that a very large number of the provincial supply concerns issue no special regulations, but insist only upon the regulations of the Phœnix Fire Insurance Office.

ON THE MOTIONS OF THE LUMINOUS GLOW IN RAREFIED GASES PRODUCED BY ELECTRIC OSCILLATIONS.*†

BY J. ELSTER AND H. GEITEL.

In the course of some experiments on cathode rays, in which a high-tension transformer was used instead of an induction coil, we observed in a Lenard tube‡ a peculiar discharge phenomenon, the nature of which we endeavoured to elucidate by a series of experiments.

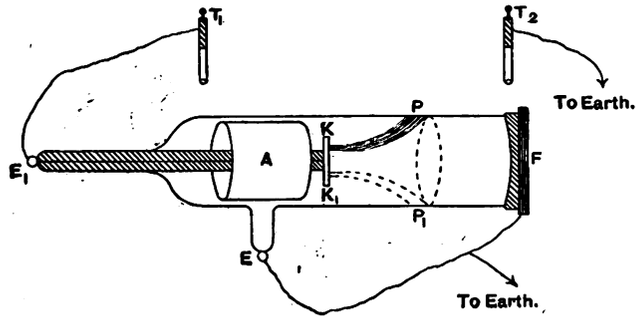


FIG. 1.

For transforming the alternate current of a large induction coil of about 18cm. maximum sparking distance, we employed the arrangement described by Tuma§; the discharge of the attached condenser of large capacity took place between two adjustable zinc terminals, the distance of which in these experiments only amounted to ½mm. to 1mm. (with larger distances the discharge tube ran the risk of percussion). On joining the aluminium disc K (Fig. 1) with the terminal T_1 of the transformer, while putting the other, T_2, as well as the cylindrical electrode A and the metal cap F, to earth, we observed at a pressure of about 1mm. the following phenomenon:—

From the electrode K there proceeded a fine light thread K P, bent upwards, which produced vivid phosphorescence both where it originated on the metallic plate and where it impinged upon the glass wall. The phosphorescent patch on the (oxidised) aluminium disc had a bluish white and on the glass the well-known green

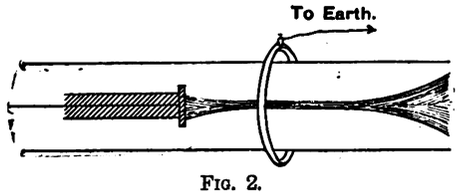

FIG. 2.

colour. Both patches increased in brilliance as rarefaction was carried further, while the luminous thread connecting them steadily decreased in luminosity and almost totally disappeared at the highest attainable rarefactions. Thus the impression was created of a fine cathode ray, bent upwards, proceeding from the plate K. If a conductor put to earth, say the hand, was brought near this ray from above, it jumped into the position $K_1 P_1$ (shown dotted in the figure). On passing the hand slowly round, the patch P passed in succession through the positions indicated by the circle P P'. The luminous thread K P was always urged on to the opposite side of the glass tube away from the conductor—was, in fact, repelled by it. Insulated conductors acted in the same manner, but much less powerfully. Dielectrics had no effect. The bending upwards of the ray was evidently due to the fact that the discharge tube was rather close to the working bench. The effect of this could be eliminated by placing a metal ring put to earth round the tube. The patch then moved into the centre of the plate K, and the luminous ray assumed the shape shown in Fig. 2 without losing its sensibility to conductors approaching from outside.

To follow up the phenomenon further, we now replaced the Lenard tube by a vessel of the shape shown in Fig. 3. In this apparatus the aluminium ring A corresponds to the cylindrical sheet of the Lenard tube, the metal cap bearing the aluminium window having been dispensed with as unnecessary. Exhaustion

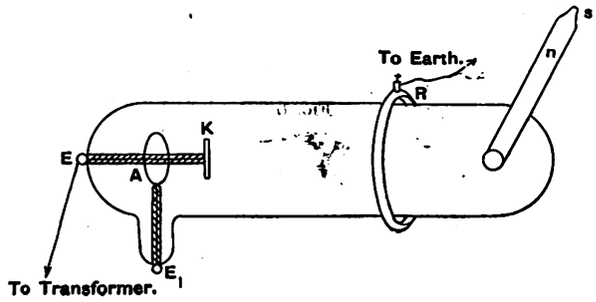

FIG. 3.

was carried on while the induction coil discharges passed through the tube until the sparks began to pass outside between the terminals E and E_1; then the apparatus was fused off the pump at *s*.

The connecting tube *n* served as a handle, being screwed into a wooden clamp. The fusing point *s* is the most endangered piece of the apparatus. On the approach of conductors sparks are easily produced here which puncture the glass. The ring R, which may be replaced by a thin annular wire, is placed at such a distance from K that the movable discharge is formed in the greatest intensity. Its appearance depends upon the distance between the conductors K and R. With high vacua it disappears completely when the ring R is brought very close to the plate, or is placed in such a position that K lies in the plane of R.

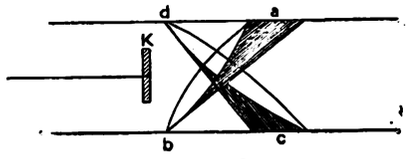

FIG. 4.

After having convinced ourselves that it was possible in this manner to prepare vacuum tubes which would constantly exhibit these phenomena, we next endeavoured to determine the direction of the current in the movable thread of light. For this purpose we introduced such a tube between the poles of an electro-magnet provided with a commutator.

This information would be given by the behaviour of the discharge in the magnetic field. For if K (Fig. 4) is a metallic plate from which cathode rays issue normally to the surface, these are not freely developed in a magnetic field; they are deflected like a current thread fastened at one end, and produce on the cylindrical glass wall a phosphorescent patch, which, according to the position

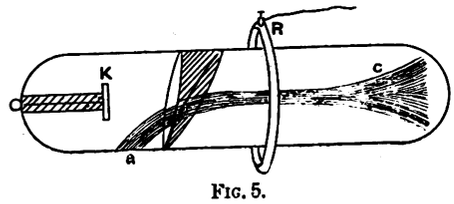

FIG. 5.

of the commutator in the circuit, assumes the position *a b* or *c d*. The tube is supposed to be in an equatorial position.

In the first place, the ring R was placed so that the phenomenon shown in Fig. 2 took place; then the electro-magnet was excited. The result was that while the cathode rays proceeding from R were deflected upwards, the phosphorescent patch produced by the movable light thread shifted from the plate K down to the glass wall, or *vice versâ* (*see* Figs. 5 and 6).

This implies that while the former are due to an electric motion proceeding from K as a cathode, the movable discharge must have its cathode at *c*, and that the two lengths represent the opposite phases of an electric oscillation. The mobility of the latter may

* *Wied. Annalen*, Vol. LVI., No. 12, p. 733.

† Movable light bands and brushes in a vacuum have already been investigated and described by Tesla (*see* Martin, "Tesla's Investigations," &c.), but we have considered the following short description of our experiments to be not superfluous on account of the simplicity of the arrangements, and the conclusion to be drawn from them concerning the nature of the movable discharge.—AUTHORS.

‡ *See* P. Lenard, *Wied. Ann.*, LI., Plate IV., Fig. 1. *See* also *The Electrician*, Vol. XXXIII., May 25, 1894, p. 108.

§ J. Tuma, *Wien. Ber.*, 102, Part 2A, p. 1,352, 1894.

Digitized by Google

therefore be due to the fact that the cathode is not a metallic equipotential surface, but a plane in either the glass or the gaseous space whose position may be displaced by approaching conductors.

In the above experiments the discharges were introduced by means of a metallic electrode. Now we endeavoured to simplify matters by using an electrodeless glass cylinder 5cm. wide and 25cm. long, the two ends of which were closed by plate glass. A spherical terminal 1cm. in diameter was in contact with one of these (*see* Figs. 7 to 10), and was connected with the free terminal

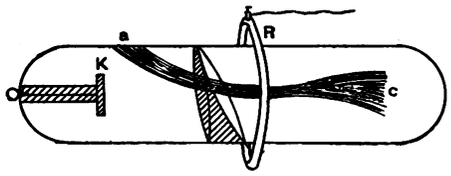

FIG. 6

of the transformer. With a suitable distance of the ring R from the electrode K, and with a sufficiently high vacuum (0·01mm. to 0·001mm. of mercury), there appeared, besides the phosphorescence of g_1, under the influence of the cathode rays proceeding g_2, a bluish pencil of light at c (Fig. 7), which contracted in the centre of the ring M to a narrow band, increasing slightly in diameter from M to a, and producing at a on the glass plate g_1 an intensely green phosphorescent circular patch of about 1cm. diameter. In this case, also, the luminous thread M a was highly sensitive to neighbouring

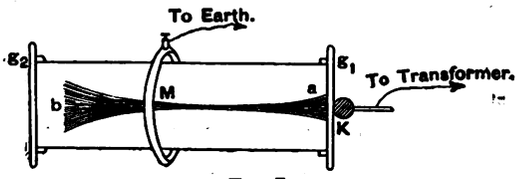

FIG. 7.

conductors. In the magnetic field it assumed, according to the position of the commutator in the circuit of the electro-magnet, the positions shown in Fig. 8 and Fig. 9. The phosphorescent spot is always designated by a.

We made sure, by a direct experiment upon a thin copper wire lightly suspended between the poles of the same electro-magnet, and traversed by a constant current, that this band of light behaves to magnetic forces as if it were traversed by a current from a to b. While, therefore, the cathode rays produced by K are directed from

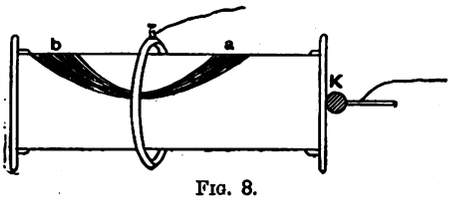

FIG. 8.

g_1 to g_2, as proved by the phosphorescence of g_2 as well as its behaviour in the magnetic field, those produced in the movable band of light follow the reverse direction, from b to a.

Here, then, we obtain the same result as with tubes with flat metallic electrodes.

It might be argued that the movable phosphorescent patch is caused by the cathode rays proceeding from K, and reflected by the opposite wall. Although the behaviour of the phenomenon in the magnetic field contradicts this view (in Figs. 5 and 6 the

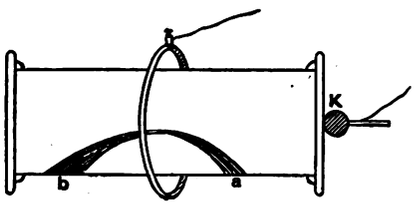

FIG. 9.

cathode rays proceeding from K do not reach the opposite wall at all), we thought better to decide this question definitely. We placed in the electrodeless vessel (Fig. 7), at an angle to the axis of the tube, an elliptical plane mica plate $m n$ (Fig. 10), which would reflect the cathode rays proceeding from g_1 on to the wall of the cylinder. The discharge shown in Fig. 10 shows distinctly that the thread of light $a b$ is *not* at right angles to the reflecting plane. The phosphorescent patch at a can therefore not be explained by the reflection of the cathode rays from g_1 at the mica plate.

Another conclusion also follows from this. Since the cathode rays producing the phosphorescent patch a are not perpendicular to the mica plate $m n$ (as is always the case when such cathode rays are formed at the surface of conductors or dielectrics), it may be assumed that their origin is not at the surface of contact between the mica and the rarefied gas. We are obliged to seek their origin in the gaseous space, and must consider that within the oscillating gas column the (as yet unknown) conditions are fulfilled which determine the genesis of the cathode rays. The gas column which is made luminous by rapid electric oscillations is therefore the origin of the cathode rays, and always produces phosphorescence when it impinges upon the glass wall of the tube. Since its position is entirely dependent upon the capacity conditions of the discharge tube regarded as a condenser—the discharge always going along that side of the tube which has the smallest capacity, and therefore first attains the discharge potential, this column and its cathode rays change with every change of capacity, as produced by the approach of conductors on one side. It always recedes from the conductor, since this increases the capacity on that side of the tube.

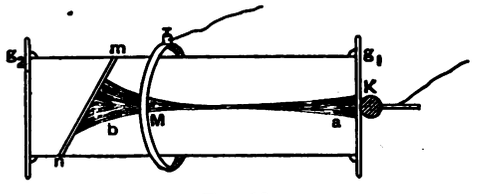

FIG. 10.

If the interpretation of the phenomenon described is correct, it will give a further proof for the view of the nature of cathode rays founded by Hertz, Jaumann,* Lenard, E. Wiedemann, and Ebert, according to which these are not due to projected electrode matter, but to motions in the ether akin to light.

THE DISTRIBUTION OF POWER IN COLLIERIES.†

BY LLEWELYN B. ATKINSON.

The present position of the coal-mining industry in the United Kingdom is one deserving of the most thoughtful consideration by all who are interested in the future of the commerce of the country, and the object of the present Paper is to point out how, possibly, some of the difficulties under which this industry at present labours may be met. The difficulty to be contended with may be briefly stated. The possible output, and, indeed, the output at which a reasonable profit can be earned, is greater than the demand at present prices; and even this demand is threatened by the decreasing price of coal raised in other countries. From whatever point of view it is looked at, this question resolves itself into stimulating demand, which can be effectually done only by lowering the selling price, and this cannot at present be done without extinguishing the profit. To decrease the cost at the collieries, there are broadly three courses: (1) to decrease the payment per ton to the mineral owner; (2) to decrease the wages cost per ton raised; (3) to decrease the fuel expenditure per ton raised. The first of these is a matter outside the scope of this Paper, the second will be briefly touched upon, and the third will be dealt with in some detail.

In the course of the last eight or nine years the author has been in close contact with mining operations in various parts of England and Wales, and the opinion has gradually been forced upon him that there is a very large margin of economy in wages and fuel to be effected. This arises from the fact that economies in labour and fuel which are studied and made use of in engineering and manufacturing industries are hardly considered in coal mining, at all events in the majority of instances. This broad fact must appeal to every mind: that, whereas in almost every manufacturing process or industrial operation the product per man has probably doubled, and the consumption of fuel been halved within the last 15 years, in coal mining the product per man has been practically stationary, and the cost of fuel per ton raised probably nearly so. This is frequently attributed to the stringency of mining legislation; but legislation has also largely affected other industries, and the result cannot be altogether attributed to this cause. It would be a long task to enumerate the causes which, in the author's opinion, contribute to this result; but, broadly, it appears to him that what is required is to do in mining what has been done in every other department of industry—lower the cost of wages and material per ton by increasing the product per man and per pound of fuel by the following means:—(1) Improved organisation, both

† From a Paper read before the South Wales Institute of Engineers.

Digitized by Google

scheme of working a colliery, and in the means for doing it; (2) more superintendence and supervision underground by thoroughly well-informed mining and mechanical engineers; (3) the greater use of mechanical power instead of human and horse labour, and more economical production of that power. In short, substitute brains and mechanical power for human labour.

It has been already stated that the immediate object of this Paper is to deal with the question of the economical production of power; but a few remarks on the subject of mechanical power in collieries may be useful. The getting of coal resolves itself into cutting and filling and hauling to the pit bottom. In the great majority of collieries both cutting and filling are done without any use of mechanical power whatever, and the progress made in introducing mechanical coal-cutters is slow, at all events in this country. A considerable experience, extending over some years, with coal-cutting machines in various collieries and various parts of the country justifies the author in saying that there are hardly any seams under 3ft. 6in. in thickness that could not be more cheaply worked by mechanical coal-cutters than by hand labour, and with a better product of round coal, but that in probably not 5 per cent. of the collieries of the country is the existing organisation of the filling and haulage sufficiently good to enable machines to be worked with that regularity which will make them pay. This is the secret of the otherwise unexplained fact that some few collieries have been and are worked by machinery with marked success, whilst the reverse holds good of the majority of cases in which it has been tried. Organisation and superintendence, those are the only secrets of cutting coal by machinery; till they are forthcoming, mechanical assistance in this direction must be postponed. In thin seams much might, no doubt, be done to apply mechanical power to reduce labour and breakage in filling the coal, but the same remark applies as to coal-cutting. The use of machinery in the coal face would so much reduce the length of face under work for a given output that the roads on to the face—being less in total length—could, without increased cost, be kept in a condition enabling mechanical haulage to be used right up to the face, doing away with horses and ponies altogether. These are some of the directions in which mechanical power may be looked for to profitably enable the output per man to be increased. But before this can be done much will have to be done to improve the general organisation both above and below ground. And this may well be commenced by the economical laying-out and conduct of the arrangements for the generation of power above ground. Consider the conditions under which this is at present carried out.

Generally speaking, when sinking operations are completed, a winding engine is put down. Subsequently, as the workings extend, haulage is considered, and some plant—either steam, compressed air, or electrical—is provided for this. Later, perhaps, pumping becomes necessary, and again a plant, perhaps, on another system is put in. There are various engines at the surface for the screening, repairing shop, and other purposes. All these are of uneconomical types; so there ensues, at every point, waste of heat and waste of steam, particularly when, as in some cases, separate boilers are put down for each plant. And the answer to any criticism generally takes the form: "Oh, fuel is so cheap at a colliery that it does not matter." Why is the fuel so cheap—that is, of such low value? Because it is so small—smashed in hewing, smashed in filling, smashed on the screens, due to imperfect methods and appliances at every point. But, at any rate, it is worth at least 2s. 6d. per ton, and it is estimated that from 5 per cent. up to even 10 per cent. of the total output by weight of the collieries is consumed at the surface, and this means, even taking the lower figure, about 9,500,000 tons, worth about £1,190,000 per annum. It has been stated by Mr. Forster Brown that the probable consumption of coal in colliery engines, taking an average, would be not less than 6lb. per horse-power hour. Taking this to refer to indicated horse-power, it is possible to produce the same power with 1½lb. of coal, or even less; hence it may be fairly said that there is a possible saving to be effected of 75 per cent., worth annually nearly £900,000. It would probably be well within the mark to say that the saving to be effected in labour of handling, and in the maintenance of boilers and appliances for consuming this, would be worth, say, 65 per cent. of the above sum, showing a possible economy of, say, £1,500,000 per annum, a sum equal to over 2 per cent. on the total value of the coal raised, or about 3¾ per cent. of the whole wages annually paid in the mining industries; and if the coal were raised unbroken, so that its value was equal to the average value of the coal sold, these figures would rise to 3 per cent. of the value of the total coal raised, or 6 per cent. of the wages paid. It may be stated at once that, to realise these economies, the power required must be produced by compound or triple expansion condensing engines, appliances almost unknown in colliery work, and to do this there is no doubt that the question resolves itself into the production of the whole power required at the colliery in one or at most two engines, and its distribution with as little loss as possible to the points where power is required. There are various methods of distributing power, but some of them are applicable only to particular cases, or in particular circumstances; the only two of general applicability are compressed air and electricity. Of these, while under favourable circumstances compressed air can be made to give a favourable efficiency, its application in mining is discounted by two important considerations of economy. To utilise compressed air with efficiency (1) the pipes must be free from leakage, (2) the air must be heated before being used. These two conditions are practically unrealisable, and hence the efficiency of air transmission in collieries is, and must necessarily be, low. The cost of plant and extended air-mains is also high. There is an advantage in compressed air that to some extent it admits of storage, and therefore the power-producing plant may be fully loaded, producing the average requirement, which, as will be presently shown, is considerably less than the maximum. With this one exception of storage, the advantage in point of view of efficiency as a means of distributing electric-motive power remains with electricity; and the economy of the cables compared with air-mains, and the facility for extension and alterations in the position of the machinery, make electricity an ideal means of distributing power.

There is, however, an objection to which I must refer—viz., the question of safety. This question of safety is one which, from the first introduction of electricity in mining, has been prominently before engineers; but it may be noted that among those who have had practical experience of its use in mines the objection is rarely raised. In a Paper read in 1891 before the Institution of Civil Engineers by the author, in conjunction with Mr. C. W. Atkinson, this question was somewhat fully dealt with, and certain conclusions were arrived at which time and experience have gone to prove the correctness of; but, as this question is to some minds still an open one, and as additional experience has added to the knowledge of the subject, it may be well to deal with it at some length. There are two distinct questions: (1) the safety of an electric motor, which may spark at the commutator; (2) the safety of a system of cables, which may be ruptured while carrying an electric current.

Dealing with the first of these, it has been shown from various considerations and by practical tests that with the amount of sparking which exists with electric motors of good construction it is impossible to ignite fire-damp, owing to the fact that the temperature is never sufficiently high, and it is only therefore in exceptionally abnormal circumstances, such as a brush falling out of its holder, or becoming displaced absolutely on the commutator, that the inflammation of fire-damp can be effected; and it has also been shown conclusively by experiment that there are in the market methods of enclosing either the whole machine, or the armature and commutator, or the commutator alone, which, even under these abnormal circumstances, entirely prevent either the access of fire-damp or the ignition of fire-damp outside the machine. Practical experience is in accord with experiment and with the principles named, and the author knows of no recorded instance where there has been any accident from the use of an electric motor in a coal mine. As regards the second point in the question of safety—viz., the possible breakage of a cable—this may be at once overcome if the cables are buried below the surface; but, as this method has the disadvantage of expense, and frequently of deterioration of the cable, we may consider the case of a cable hung from the walls or timbers. In this case, if the cable does break, the ends are quickly parted; the spark may continue for the fraction of a second, but it has been shown by the experiments of Messrs. Wüllner and Lehmann, at Aix-la-Chapelle, which experiments were accepted by the Prussian Fire-damp Commission, "that even violent sparks from rupture of the current, accompanied with the explosion of fragments of iron in a state of combustion, had no effect on the inflammation of fire-damp."

Considerable light has, in the author's opinion, been thrown on this question by the facts recently stated by Prof. Vivian B. Lewes. It appears that the ignition of fire-damp arises in most cases, not from the raising of the temperature to the ignition point of fire-damp, which is very high, but by the raising of it to the point of its decomposition with evolution of hydrogen, which, becoming ignited, eventually ignites the firedamp. This requires two things: (1) Time (and Prof. V. Lewes states that 10sec. is in some cases necessary); (2) the maintaining of a particular mass of gas in contact with the point where the heat is developed long enough to effect the operation quoted. Neither at the commutator of a motor, or in the case of a ruptured cable, are these conditions fulfilled. In the face of the facts and experiments and experience now at disposal, in the author's opinion, those who raise the objection to electricity in mining on the ground of safety ought to bring some proofs of that danger, if it is to receive consideration. Notwithstanding the extended use of electricity, these accidents do not occur, and, in the opinion of many well qualified to give it, the danger arising from electricity is less than that arising from safety lamps, and enormously less than that arising from almost any explosive agent now in daily use.

Having dealt with this question, it remains to be asked: Is the present position of power distribution by electricity such that we

Digitized by Google

in the working and more especially in the original laying-out of the may use it with confidence for the whole of a power required at a colliery? The author's answer to this is, Yes. In support of this may be given the following facts. The largest engine at a colliery is the winding engine, and, supposing this to require to be capable of developing power at full speed of 1,000 H.P., which is an outside figure, this could be well replaced by two motors of 500 H.P., one on each end of the shaft of the drum, without gearing. There are numerous cases of dynamos and motors of this power working with ease and satisfaction and giving no difficulty whatever, and operated by ordinary mechanics with no more trouble than an ordinary steam engine.

Motors of smaller sizes are in use all over the world, and with universal satisfaction as to ease of manipulation and low cost of maintenance. Are the claims made for efficiency of electric distribution of power realised? On this point the author has examined carefully tests made by himself and by others on electric power plants and has arrived at this conclusion: while the efficiency of distributing electric power and its utilisation in the motors come up to that claimed, the efficiency of the production of electricity is not, as a rule, as high as is claimed, or as high as may be realised. The reason is this: sufficient account is not taken of the fact that the average load is considerably less than the maximum requirement. While the efficiency of electric generation—that is, the proportion between the electric power delivered to the cables and the indicated horse power of the engine—is as high as 86 per cent. at full load, it falls to 74 per cent. at half load and to about 58 per cent. at one-quarter load. The reason for this is to be found in the power the engine takes to drive itself. The engine is generally arranged to work with an economical cut-off at the full load or maximum power, and consequently is larger than necessary for all smaller loads. It should be arranged to work with an economical cut-off at the average power; then at a larger power, although the consumption of steam per indicated horse power would be somewhat larger, the mechanical efficiency would be so much better at the average load that considerable economy, and, indeed, the best possible result, would be obtained. The moral is to use engines with automatic expansion valves, permitting the engine, if a simple one, to work with a cut-off as late as one-half or five-eighths of the stroke when developing the maximum power, and working with a more economical grade of expansion at the average load.

To apply the principles advocated in this Paper, the method to be adopted should be as follows: when a colliery is opened, an estimate must be made of the power which will ultimately be required for the whole colliery. It need not be all provided for at once, but the arrangements must be such that what is provided will be worked at an economical load, and that by simple duplication it may be increased. Suppose an example is taken which may be considered to represent an average case, where there is no very heavy pumping.

Table of Power Required at a Colliery.

—	Max. power. H.P.	Aver. power. H.P.	Min. power. H.P.
Winding	700	225	0
Fan engine	60	60	60
Pumps (say)	50	50	50
Haulage	200	100	0
Lighting	20	10	10
Screens	20	20	20
Shops at surface	20	5	5
Capstans for waggon handling.	20	10	10
Total	1,090	480	155

The power required by the winding and haulage engines is what would probably be required in a colliery drawing about 1,500 tons per day, and the maximum power required by the winding engine is reckoned on the assumption that the weight of the ropes is unbalanced, and the average upon the assumption that the winding takes 40sec, and the unloading and loading 25sec. Variations will correspondingly affect these points, and must be made to suit each case. These powers are those required at the separate machines, and, if we take it that the loss in the cables at full load is 5 per cent., which will be ample, as the bulk of the power is not far from the source, and that at the average load and upwards the indicated power is $\frac{100}{86}$ of the power delivered to the cables—we get the following as the indicated power required at each load, which, assuming that the electric motor will transform only as much electric power into mechanical power as a steam engine would convert of indicated power into mechanical power, gives a direct comparison between the actual indicated power required if all the engines were worked direct from the boiler or by the distribution thus to be effected.

Indicated Horse-power of Generating Engines.

Maximum.	Average.	Minimum.
$\frac{100}{86}\times\frac{100}{95}\times 1{,}090$; $=1330$	$\frac{100}{86}\times\frac{100}{97\cdot5}\times 480$; $=572$	$\frac{100}{64}\times\frac{100}{95}\times 155$. $=255$

Now, it will be observed that the average power is 572 I.H.P., as compared with 480 I.H.P. actually required at the engines. But taking for the former Mr. Forster Brown's figure of 6lb., and for the latter 1½lb., the economy resulting is found from the fraction:—

$$\frac{6}{15\times\frac{47\frac{1}{2}}{480}} \text{ or } \frac{6}{1\cdot78} \text{ or } \frac{100}{9\,6}$$

not far differing from the possible economy spoken of early in the Paper. That such figures are realisable in practice is shown by the figures given in a Paper read before the North of England Institute of Mining Engineers by Mr. Alexander Siemens. Tests are there recorded where, with a plant considerably smaller than that here considered, a consumption of 2·62lb. per E.H.P. hour, equivalent to 2·25lb. per I.H.P. hour, was obtained; and in the discussion on the same Paper reference was made by Mr. D. B. Morison to a plant using 2lb. coal per E.H.P. equivalent to 1·72lb. per I.H.P. The use of triple-expansion instead of compound engines would further reduce this to the figures named above.

The writer is aware that in thus advocating the generation of the whole of the power in one engine or pair of engines he is advising a very radical departure from existing and well-tried methods; but the advantage in economy is so great that, in his view, a revision of method must take place, and in any case the subject is well worthy of consideration and discussion.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January 3, 1896.*

Acetylene Gas.—The financial interests which control the Willson patents on the production of carbide of calcium and acetylene gas have apparently been very successful in disposing of local rights. A strong company just formed has purchased rights for New York and neighbouring cities, and the gas magnate of Boston, Mr. J. Edwards Addicks, has acquired the exclusive rights for that city. The parent concern, the Electro-Gas Company, claims that calcic carbide can be produced at the rate of $15 per ton, and acetylene gas itself at $37.50 a ton. This estimate is based upon a cost of $6 per day of 12 hours for 180 electrical horse-power, and otherwise merely included labour and the cost of raw materials. Even the above price is a considerable advance over the claims first made by the original Willson Company, which placed the cost at $5 to $6 per ton. As the validity of the Willson patents is very doubtful, it is considered surprising that those exploiting them have met with such great success.

An Interesting Strike.—The trolley strike which ended in Philadelphia last week developed several features of interest. Owing to the action of the Union Traction Company in ceasing to grant free transfers, as had been the custom of the separate companies of which it was recently formed, the public had become very much incensed against it. As a consequence the strikers had the full sympathy of the people, who even went so far as to refuse to patronise cars run by non-union men. The strikers hired many hundreds of teams for use during the morning and evening hours of travel and transported passengers for five cents, the usual street-car rate, granting transfers from one wagon to another. The result was as might have been foreseen—the street railroad company being compelled to come to terms.

Difficulties in Polyphase Working.—It is reported that some difficulties are being experienced in the operation of some of the polyphase plants recently installed in this country. While no definite information can be obtained, it appears that the trouble arises from the fact that if a close balance is not kept among the several polyphase circuits very unsatisfactory results in working are obtained. There is a rumour that in one large station where polyphase machinery was installed, the original machines will be replaced by simple alternators with shafts rigidly coupled in such a manner as to produce the necessary difference of phase between the currents from the several alternators thus disposed.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *Jan. 14, 1896.*

The Laval Steam Turbine.—At the meeting of the Société Internationale des Electriciens on the 8th inst., M. Fayot read a Paper on the latest results obtained from the trials of the Laval steam turbine. A 50 H.P. turbine was tested at a steam pressure of 5 kilogrammes per square centimetre (71lb. per square inch) and gave a consumption of 10·58 kilogrammes of steam per horse-power hour. Two other trials, made at the Bordeaux Exhibition at full load (100 H.P.) for seven hours at a boiler-pressure of 8 kilogrammes (113lb. per square inch) and a vacuum of 66 centimetres in the condenser, resulted in a consumption of 9·16 kilogrammes of steam per horse-power-hour. With a load of 50 H.P. there was a consumption of 10·8 kilogrammes of steam. A third trial after nine months' use resulted in a consumption of 8·9 kilogrammes per horse-power-hour on a 10 hour trial. A fourth test at Troyes on a 20 H.P. turbine driving shafting which drove four dynamos gave a consumption of 8·9 kilogrammes of steam, the pressure being 5 kilogrammes (71lb. per square inch). In a fifth trial made with a 75 H.P. turbine at the Magasins de la Place Clichy, with a steam pressure of 12 kilogrammes (170lb. per square inch) and a 65-centimetre vacuum in the condenser, the consumption was 10·5 kilogrammes per horse-power-hour. M. Fayot then touched the question of the variation of the steam consumption with the output and the number of nozzles. M. Hillairet asked what the consumption was on starting. M. Fayot replied that it was 30 to 35 per cent. more than the normal amount. M. Arnoux observed that it was quite possible to show why the efficiency was greater with larger turbines: it was due to the fact that the speed of the vanes was greater with large turbines; in turbines of 200 H.P. this speed was 400 metres per second, whilst in 75 H.P. turbines it was only 60 metres per second.

The Blot Accumulator.—At the same meeting of the Société Internationale des Electriciens M. d'Arsonval gave some particulars with regard to the Blot accumulator. He commenced by short-circuiting two 100-ampere cells and reddened a piece of wire, the experiment lasting during the reading of his Paper. These accumulators are of the pure Planté type and present a surface of 1·2 sq. metre for every three kilogrammes of plate. M. d'Arsonval gave the results of his own tests and of some made by Mr. Preece in London in February, 1895, and early this month. An accumulator was short-circuited for 10 minutes, and gave 200 amperes. It was then discharged, charged and discharged at the rate of 1 ampere per kilogramme. It gave a capacity efficiency of 79·2 per cent., and an energy efficiency of 64 per cent. No mud was observable at the bottom of the vessel, and the plates were in a perfect condition. Other tests gave capacity and energy efficiencies of respectively 84 per cent. and 78 per cent. Capacities of from 10 to 12 ampere-hours per kilogramme were obtained. M. d'Arsonval remarked that he was much struck with the way in which these accumulators retained their charge. For instance, a battery which was charged on July 4th was only discharged on October 24th, and next to none of the charge had been lost. Again, two cells were put on short circuit for 24 hours without injury. These qualities, he thought, would make these accumulators valuable for the Concarneaux laboratory, which is on the sea coast, and where wind is used to drive the dynamo to charge the accumulators, and where the cells may therefore be subjected to very trying rates of charge and discharge. In reply to Lieut. Darrieux, M. d'Arsonval gave the following figures:—

Rate of discharge.	Efficiency.
1 ampere per kilogramme.	89% in ampere-hours.
2 ditto.	75% ditto.
3 ditto.	68% ditto.
5 ditto.	50% ditto.
516 ditto.	45% ditto.

Electric and Gas Lighting in Paris.—The Auer burner has proved a serious competitor with the electric light in Paris, though some people find it as expensive as others find it economical. At the present moment there is much talk of the Denayrousse burner, which consists of an ordinary gas burner combined with a small electric air pump, which sucks in the air and forces it through the flame under pressure. The usual candle-power of this burner is about 30 to 40 carcels for a consumption of 10 litres per carcel-hour. In spite of competition, however, the electric light, notwithstanding its high price, continues to progress, and reductions of tariff are in contemplation.

Honours for French Electricians.—At the last meeting of the Société Internationale des Electriciens, M. Hospitalier announced the following "décorés":—Commanders: MM. Loewy, Marey; Officers: MM. d'Arsonval, Joubert, Leaute; Chevaliers: MM. Brylin, Guillaume.

CORRESPONDENCE.

THE AUDIT OF ELECTRIC LIGHT COMPANIES ACCOUNTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: From your Note on this subject commenting on Mr. Morse's very fair letter you seem to assume that under a sensible dispensation either the Board of Trade audit or that by the auditors of a company—you do not say which—could be done away with. May I be permitted to remind you that the expense of a Board of Trade audit (which is absolutely unnecessary and useless for the company) has been imposed upon companies by Act of Parliament, and that the audit of accounts generally is required in the interests of shareholders, and that a Government Department cannot undertake the responsibilities and duties towards shareholders that are expected from the auditors of companies. Naturally I have no objection to the audit by the Board of Trade in the interests of the local authorities being done away with, but this, which is, I fear, quite a work of supererogation so far as the company is concerned, cannot be done, having regard to the condition of the law.—Yours, &c., AUDITOR.

"BAR" AND "TROLLEY" CONTACTS ON ELECTRIC TRAMWAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your editorial remarks on the above subject, with reference to my recent investigations, published in your issue of last week, you say: "From an æsthetic point of view, the demerits of the 'bar' and 'trolley' methods are about equal; the former involves the uglier car, the latter the uglier overhead construction."

I fully agree that no overhead contact system can ever, in the strict acceptation of the term, be æsthetic; but as regards the car, may I, in cheap verse, observe that

A somewhat unæsthetic bar
May surmount a pretty car?

In proof thereof I enclose an illustration of the cars in use at Bale, these cars having, it is true, no outside seats. It is those latter which make the cars so monstrously unsightly, more especially when, in addition, they are roofed for the purpose of protecting passengers against the contingency of a shock from the overhead wire or contact piece. Riding outside is very pleasant as long as the speed does not exceed that of a jog-trot horse-car or omnibus, viz., about eight miles per hour; but when, on electric lines in suburban and country districts, a speed of 15 miles is attained (for several lines in which I am concerned a speed of even 20 miles between stations has been authorised), the effect of outside riding, especially in inclement weather or against a strong head-wind is somewhat too exhilarating, and on such lines cars with only inside seats and end platforms, carrying from 50 to 60 passengers, will not only fully accommodate the traffic but also have a pleasing appearance.—Yours, &c.,

C. S. DU RICHE PRELLER.

OVER-PRODUCTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to your leading article on "Over-production" in last week's issue, I have always maintained that, in the long run, it is conducive to the spread of applied electricity to encourage electrotechnical education as much as possible. The larger the number from which the best men are selected by the inevitable process of competition, the better. The unfit go to the wall, but they carry the light of their knowledge into other professions and callings, and public apathy as regards electrical matters is thus gradually undermined.—Yours, &c.,

W. PERREN MAYCOCK.

Croydon, January 11, 1896.

POLICE INTELLIGENCE.

On Tuesday, before the Common Serjeant, at the Central Criminal Court, James Fenton Whelan, 25, a clerk, late in the employ of Messrs. Nalder Bros. and Co., electrical engineers, of Red Lion-street, Clerkenwell, pleaded guilty to charges of forging and uttering the endorsements to orders for the payment of various sums of money, and also to stealing the money of his employers. Mr. Grain prosecuted, and Mr. Lambert watched the case for the prisoner.

In stating the facts of the case Mr. GRAIN said the prisoner had been in the employ of the prosecutors as a clerk, and it was his duty to disburse small accounts out of the petty cash. Mr. Wm. Henry Haigh, of 15, Wilmington-square, Clerkenwell, had an account owing from the firm in November last, and on November 20th he made an entry, showing that he had paid the account, which was for £2. 5s. 6d. He produced a receipt which turned out to be a forgery. On a further investigation of the accounts it was discovered that a cheque for £2. 14s. 6d., which had been drawn by the firm in payment of an account due to a Mr. Turnbull. This cheque the prisoner endorsed and cashed, as he did also a cheque for £3. 13s. 6d. drawn in October in favour of the same firm. The receipted accounts were forgeries, as were two other accounts for small sums alleged to have been paid the same firm. The prisoner had been in the service of Messrs. Nalder Bros. for about twelve months, and his defalcations extended over a period of three months. When given into custody the prisoner begged that he might not be prosecuted, stating that it was not his fault, and that he had no intention to defraud; but the matter was so serious that the firm could not overlook it.

In reply to the Common Serjeant, Mr. GRAIN said the prisoner's total defalcations amounted to about £35.

The COMMON SERJEANT said he would deal with the case as one of embezzlement, and not as one of forgery; but the prisoner had committed a very serious offence. He seemed hitherto to have been a man of good character, and he appeared also to have been in receipt of what he could not but regard as an adequate salary. The adequacy of a salary, no doubt, depended very much upon what a man had been accustomed to, and persons employing others must be protected from such fraud as the prisoner had been guilty of. He must pass such a sentence as would prevent the prisoner again engaging in such proceedings, and a sentence, also, which would deter others in the same employment from following his example. The prisoner would be sentenced to six months' hard labour

BOOKS RECEIVED.

"Dynamo Electric Machinery." By Silvanus P. Thompson, F.R.S. Fifth Edition, Revised. (London: E. and F. N. Spon.) Price 24s.

"Elektro-Metallurgie." By Dr. W. Borchers. (London: Williams and Norgate.) Vol. II. Price 8s.

"Hazell's Annual for 1896." Edited by W. Palmer, B.A. (London: Hazell, Watson and Viney, Limited.)

"Munro and Jamieson's Pocket Book." By John Munro and Andrew Jamieson. (London: Messrs. Charles Griffin and Co., Limited.) Eleventh Edition. Price 8s. 6d.

"Lockwood's Builder's and Contractor's Price Book for 1896." Edited by Francis T. W. Miller. (London: Messrs. Crosby, Lockwood and Co.) Price 4s.

"The Intellectual Rise in Electricity." By Park Benjamin. (London: Messrs. Longmans, Green and Co.) Price 21s.

"Electricity and Magnetism." By G. C. Foster, F.R.S, and E. Atkinson. (London: Longmans, Green and Co.) Price 7s. 6d.

"Die Spectralanalyse." By Dr. John Landauer. (Brunswick: Friedrich Vieweg and Son. 1896.) Price 4s.

"An Electric Spark." By G. Manville Fenn. Second edition. (London: Methuen and Co.) Price 6s.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is in active preparation, and will be ready at the end of January. Orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. Full particulars post free on application.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

CORRECTION.—By a slip of the pen in our issue of Jan. 3rd a Trade Note, referring to the bankruptcy of Messrs. Smeaton and Bennett, electrical and general engineers, of 135, Minories, E., was made to read Smeaton and Page. This has, we learn, caused some annoyance to Mr. Page, who trades under the name of Smeeton and Page, electrical engineers, at 163, Queen Victoria-street, London, E.C. We very much regret that such a clerical error should have occurred, and should have caused Mr. Page any annoyance. The announcement should have read: "Mr. W. Izard, 52, Gracechurch-street, E.C., has been appointed trustee in the bankruptcy of Smeaton and Bennett, electrical and general engineers, 135, Minories, London, E." We need scarcely add that the announcement in no way related to the firm of Smeeton and Page, electrical engineers.

TENDERS INVITED.—The Corporation of Birkenhead invite tenders for the wiring of the Town Hall, it having been decided to light the same by electricity. Plans, &c., can be seen, and specifications obtained, at the Town Clerk's Office, Town Hall, Birkenhead, or of Mr. James N. Shoolbred, 47, Victoria-street, S.W. Tenders must be sent in to Mr. Alfred Gill, Town Clerk, Town Hall, Birkenhead, by noon of Thursday, the 23rd inst. Some further particulars are given in our advertisement columns.

——— Tenders are invited until the 22nd inst. by the Roumanian State Railways in Bucharest for the supply of 27½ tons of galvanised iron wire.

——— Tenders are invited until the 30th inst. by the General Direction of French Posts and Telegraphs, 103, Rue de Grenelle, Paris, for the supply of 53,230 prepared telegraph poles.

Digitized by Google

TENDERS INVITED.—The municipal authorities of Tuy invite tenders for the concession for the electric lighting of the town during a period of 20 years. Tenders to El Ayuntamiento de Tuy (Pontevedra), Spain.

——— The Hanover Direction of the Prussian State Railways require tenders by the 20th inst. for 191¾ tons of telegraph iron wire, 194 tons insulated wire, 33,000 porcelain insulators, and 1,400 insulator supports. Tenders to Königliche Eisenbahn Direction, Joachimstrasse No. 7, Hanover.

——— The Municipal Authorities of Parma require tenders by February 25th for the electric lighting of the town for a period of 15 years, commencing June, 1897.

——— The District Council of Swadlincote (Burton-on-Trent) invite tenders for the lighting by electricity of the thoroughfares of the township of Stanton. Particulars can be obtained from Mr. R. Cartwright, surveyor. Tenders must be in by the 27th inst.

TENDERS ACCEPTED.—Messrs. F. A. Glover and Co., of Queen Victoria-street, E.C., inform us that their tender for the electric lighting of the Agricultural Hall has been accepted. In addition to the incandescent lighting, 45 arcs, together with large mains for supplying current to the various exhibitions, are to be supplied.

——— The Gas and Electricity Committee of the Bolton Corporation have accepted the tenders of Messrs. S. Z. de Ferranti (Limited), for an additional alternator at the electricity works, and the tender of Messrs. Hick, Hargreaves and Co. for a new engine.

——— The following tenders have been accepted by the Yarmouth Town Council in connection with their electricity works: Additions to the electric lighting station—Mr. Bray, £1,146 (lowest tender); Messrs. W. J. Crampton and Co., a Davey-Paxman engine and 150-kilowatt alternator, £1,593; Crompton and Co., steam pipes, £289 10s; Babcock and Wilcox, pair of 250 H.P. boilers, £1,457 6s.

SALE BY AUCTION.—Wednesday, the 29th, has been fixed for the sale by auction, by Messrs. Wheatley Kirk, Price and Goulty, of the entire contents of the works premises known as the Electrical Works, Acton Hill, London, W. The sale commences at 10 for 11 o'clock prompt, and includes boiler, engines, shafting, fixed plant and machinery, loose tools and utensils, patterns and drawings, stock, stores, office furniture, &c. The boiler is a 50 H.P. loco.-type semi-portable by Davey, Paxman and Co., and the engines includes a Davey-Paxman 40 H.P. and a 17 H.P. "Premier" gas engine.

APPOINTMENTS VACANT.—The Government of Queensland, Australia, require applications for the post of Electrical Engineer to the Government, whose duties will be to advise the Postal Telegraph Department upon all matters connected with the telegraph, telephone and cable systems of the Colony. The salary will be £600 per annum, with travelling allowances. Further information can be obtained from the Agent-General for the Colony, 1, Victoria-street, London, S.W., and applications have to be sent in to the Agent-General by Monday, March 2nd. Some further particulars are given in our advertisement columns.

——— The Lighting Committee of the Wolverhampton Corporation invite applications for the post of assistant and draughtsman to the borough electrical engineer; commencing salary £100 per annum. Applications to Mr. F. Harman Lewis (borough electrical engineer), Town Hall, Wolverhampton, by the 23rd inst. Some further particulars are given in our advertisement columns.

——— The City Engineer's Department of the Liverpool Corporation require a senior assistant in the drawing office. Commencing salary £175 per annum. Applications must be sent in to the City Engineer, Liverpool, by Friday, the 31st inst.

APPOINTMENT.—Mr. E. E. Hoadley has been appointed an assistant electrician to the Islington Vestry Electricity Works.

ENGINE DRIVER WANTED.—The Vestry of St. Mary, Islington, require, for their electric lighting station at Eden-grove, an engine driver with large experience in driving stationary engines, preferably for electric lighting purposes. Some further particulars are given in our advertisement columns.

SALES REPRESENTATIVE.—We are informed that Mr. J. F. Poynter, of 15, Seething-lane, E.C., has been appointed sales representative for the Cruto Incandescent Lamp.

LIQUIDATIONS.—An order has been made, upon the application of Mr. Cecil Mercer, Official Receiver, of 95, Temple-chambers, Temple-avenue, E.C., that Ronald A. Scott, Annie Scott, Herbert K. Reeves, George Heaver, Godfrey Wolley, James Herbert Garrett, T. H. J. Watts and James Damer do attend to be publicly examined at the Town Hall, Brentford, on Friday, the 24th inst., at 2 o'clock.

——— We have received a summary of the liquidator's accounts in the matter of the London Metallurgical Company (Limited), which shows, after payment of Court fees and costs, a credit balance of £748. 18s. Mr. D. J. Stewart Boyle, 91-93, Palmerston-buildings, E.C., is the liquidator, and will furnish any further information required by creditors and contributories.

LIQUIDATION.—A motion came before the High Court on Tuesday for the appointment of a receiver and manager of the business of the Mersey Rubber Company (Limited). After hearing the arguments the judge appointed Mr. Mather, chartered accountant, of Bolton, receiver and manager.

LEGAL.—The case of the Gulcher (New) Electric Light and Power Company *v.* Murray came before Mr. Justice Vaughan-Williams yesterday (Thursday) on an application by the liquidator of the Company for an order of the Court calling upon Mr. James Murray to pay calls upon 300 Preference shares which it was alleged had been duly allotted to him. The respondent admitted that he agreed to take the shares, but only upon condition that at least 10s. was paid up on an issue of Preference shares. His allegation was that the condition precedent had not been carried out, and that therefore he was not liable. Judgment was reserved till this (Friday) morning.

TELEGRAPH MATERIAL FOR AUSTRALIA.—Messrs. Felten and Guilleaume, of Carlswerk, Mulheim-on-Rhine, have secured an order for 60 tons of copper wire, 120 tons of galvanised iron telegraph wire, and 20 miles of insulated copper wire for the New South Wales Posts and Telegraph Department.

TELEGRAPHIC WIRE AND APPARATUS.—There was a revival in the export trade of this country in telegraphic wire and apparatus connected therewith during last month, the exports reaching £296,145, compared to £70,459 in the previous month, and £41,152 in the corresponding month of 1894. The returns for 1895, however, are the smallest for several years past, amounting to £789,810, against £1,386,614 in 1894.

TELEPHONE TRUNK LINES.—The following towns are now connected with telephone trunk lines by means of which communication can be made between Post Office and National Telephone subscribers, or *vice versâ*, on payment of the fees: Belfast, Birmingham, Brighton, Bristol, Cardiff, Chelmsford, Colchester, Dublin, Edinburgh, Exeter, Glasgow, Hexham, Hull, Ipswich, Leeds, Leicester, Liverpool, London, Manchester, Morpeth, Newcastle-on-Tyne, Newport (Mon.), Nottingham, Nuneaton, Plymouth and Sheffield.

TRADE IN 1895.—Messrs. Bennett and Druce, of Preston, report a moderately busy year, with improved trade prospects for 1896. The installations carried out by the firm during 1895 include St. Joseph's Catholic Church, Preston, which has a gas engine plant, with storage batteries, and includes an electric organ blower; 600 incandescents and several arc lights for the new sheds at the Salford Docks, a motor installation at the offices of the *Preston Herald*, an electric heating and ventilating system for the Preston Industrial Co-operative Society, and also a 10 H.P. hoist. This firm's speciality is the installation of the electric light in cotton mills, and nearly 10,000 8 c.p. lamps have now been fixed in these mills by Messrs. Bennett and Druce. The firm complain of a somewhat reckless cutting of prices in the Manchester district, but report that the general tendency seems to be towards better work and fairer prices.

"EXPORT MERCHANT SHIPPERS' DIRECTORY."—We have received from Messrs. Dean and Son (Limited), of 160A, Fleet-street, London, a copy of the above publication, which is in its 31st year. The price of the Directory is 15s., and to all interested in exporting the book should prove of great value. The contents include a list of the consuls of foreign States in London, shipping and forwarding agents, steamship lines and navigation companies, chambers of trade and commerce, very complete information regarding Lloyds' signal stations, agents, &c., excise allowances and drawbacks, tariffs, &c., and an alphabetical list of merchants with their respective trade ports and class of goods shipped. In addition there is an alphabetical list of places of shipment. Nearly 1,400 large 8vo pages are packed with information of service to traders generally.

CALENDARS.—The Calendars for 1896 show a more than usual variety. We have received from the Sandycroft Foundry and Engine Works Company a well-printed hanging sheet calendar, with illustrations showing the special types of mining and electrical machinery made by the Company, including the "Keith" electric locomotive for carrying and hauling, of which a good view is shown.——The Chloride Electrical Storage Syndicate send a neat little watch-pocket calendar and memorandum book, which, being strongly bound, is useful as well as ornamental.

ABERDEEN.—Considerable interest was evinced in the Aberdeen Fish Market last week on the arrival of the "Campania," a Hull trawler, which put into Aberdeen to discharge. The trawler is one of the few fishing boats which may be termed up-to-date. It is fitted throughout for the electric light, and her catch was discharged at Aberdeen under the beams of electricity to the astonishment of a large crowd of on-lookers. The "Campania" has been fitted out by Messrs. Clarke, Chapman and Co., of Gateshead-on-Tyne.

Digitized by Google

AMBLESIDE.—The result of the correspondence between the District Council and the Board of Trade on the question of the application of the Windermere and District Electric Supply Company for a Provisional Order to light this district electrically is a notification from the Board that, in order to successfully oppose the Company's application, it will be necessary for the Council themselves to apply for an Order.

ASHTON-UNDER-LYNE.—The Town Council are considering the desirability of erecting a refuse destructor station in conjunction with their proposed electric light works. It has been decided to insert advertisements in the local newspapers inviting tradesmen and ratepayers to state whether they would be prepared to adopt the electric light if produced and supplied by the Corporation at a charge not exceeding 8d. per unit.

BATTERSEA (LONDON).—In response to the invitation of the Battersea Vestry, offering premiums to consulting engineers and contractors for the best schemes, reports, designs, plans and estimates for lighting the district by electricity, 21 such schemes have been received, and are now under examination by Mr. Robert Hammond, who has been appointed by the Vestry their electrical adviser.

BOLTON.—At the last meeting of the Gas and Electricity Committee a number of applications for the extension of the electric light mains were before the Committee.

BRADFORD.—Mr. W. C. Dixon on Tuesday presented the minutes of the Gas and Electricity Supply Committee, which included a resolution to purchase two plots of land, a portion of which is required for the purpose of extending the Corporation's electricity works. Another resolution invited the Council to authorise the provision of additional engines and plant at an estimated cost of £11,000, and to apply to the Local Government Board for the necessary borrowing powers. Mr. Dixon stated that the present supply station was quite inadequate for the requirements of the borough, and the proposed site was the most desirable from every point of view. They would be able to put down plant upon the triple-expansion principle and upon the surface-condensing principle. A beck ran through part of the land that would supply the necessary water for condensing purposes, and would be easy of approach. The Committee had been called upon during the past year for much more electric current than they had been able to supply. They had even had to ask the Corporation to allow them to cut off the supply of current to the Town Hall and the markets. Owing to the sanction for new plant, which the Committee asked for last year, not being granted in time, it was so late before the new engines and boilers could be got to work that it was impossible to cope with the demand. The extensions were estimated to cost a total of about £31,000, of which £22,000 would have to be met during the present financial year. The proposed new machinery consisted of two new 600 H.P. triple-expansion engines and the requisite dynamos. He was glad to be able to report that the electricity plant, so far as it had been established, had returned 9 per cent. upon the outlay, and after paying the interest and sinking fund, left a net profit of 3 per cent. The proposed new plant would nearly double the horse-power output of the works (5,200 H.P. against 2,800). Even if immediate sanction were given to the Committee's proposal, it would take seven months to get the engines and six months to get the dynamos and boilers, and therefore the Committee would have all their work cut out to get the new machinery into working order for next winter. Mr. Speight, who supported the Committee's proposal, complimented them upon looking from 10 to 20 years ahead, although he believed that by the use of electric motors for power purposes the demand would overtake the supply within a much shorter period. Mr. Dixon, in reply to a number of questions, said that when the new plant was erected, they would have a voltage of 500 to deal with, which would enable them to supply the remotest parts of the borough with electric current. The minutes were finally approved.

BRAZIL.—By a telegram dated January 3rd last, Her Majesty's Minister at Rio de Janeiro states that the revised Brazilian Customs tariff raises the duties by one-third, and that there are now no differential duties on British commerce.

BRISTOL.—At the meeting of the Electric Lighting Committee on Friday last extensions of the mains to Small, Quay and Nelson-streets were agreed to. It was also decided to order another alternator from Messrs. Siemens Bros. and Co. Since December 30th, 1,400 lamps have been connected.

BRIGHTON.—Mr. Arthur Wright, borough electrical engineer, presented at last night's meeting of the Council a report in which he recommends extensions of the public electric lighting to a number of additional thoroughfares. Mr. Wright recommends similar sets of 5·7 ampere lamps such as those now being erected in other parts of the town, and for the remaining streets the placing of incandescent lamps in all the street lanterns in proximity to the distributing mains in a similar manner to those in use in St. James's-avenue, where the experiment of electric lighting of side streets has been successfully tried for about 12 months. Mr. Wright sets out the reasons for these recommendations as follows:—

1. The increased illumination of the streets can be more economically effected by using electricity than by increasing the consumption of gas.

2. By electrically lighting these streets a very profitable long hour load would be put on the Corporation distributing mains and plant, which are at present practically idle after eleven o'clock at night.

3. The Lighting Committee would have the immediate control of the lighting of about 20 miles of the most important streets of the town.

4. A profit of about £1,200 per annum would accrue to the Corporation by the electricity undertaking supplying the necessary current on the present tariff.

5. The public will have the fact constantly before them that an electricity supply is available in all the streets electrically lighted.

Mr. Wright has prepared an account of the annual cost, which provides for a 50 per cent. extra candle-power over existing gas lamps, and estimates that the whole of the work can be completed by the middle of September next for a sum of about £8,000. 589 existing street gas standards are affected by the proposal. The Lighting Committee of the Corporation recommend that Mr. Wright's report be approved and acted upon forthwith, and that he be instructed to prepare specifications, upon which tenders are to be invited.

DEWSBURY.—The Corporation have decided to reduce the charge for electric current for motive power, cooking and heating purposes to 4d. per unit.

EDINBURGH.—The Joint Committee of the Cleaning and Lighting and Electric Lighting Committees of the Town Council have decided to recommend extensions of the public lighting by electricity, which will require about 230 additional lamps, the cost of which is estimated at over £4,000.

EXHIBITIONS.—The Foreign Office authorities have notified the Science and Art Department that an international exhibition is to be held at Brussels in 1897. The exhibition will comprise 14 sections, including Industrial and Decorative Arts, Lighting and Heating, Electricity—Traction, and Industrial Manufactures—materials, methods and products.

FACTORY LIGHTING.—The electric light has recently been installed in the Harrington Lace Factory, at Long Eaton. The machinery has been supplied by Messrs. J. H. Holmes and Co.

FAREHAM.—Electric lighting matters progress slowly, and the relations between the Company and the members of the District Council seem to grow more embittered as time goes on. The *Portsmouth Times* makes a very sensible suggestion that some gentleman of light and leading should be invited to mediate between the parties. The Company's offer to compromise the matter is now directly before the Council, who are invited to come to an arrangement promptly.

FIRE ALARMS.—A labourer named Crook was fined £10, with the alternative of six weeks' hard labour, for breaking the glass face of an electric fire alarm. Mr. Corser, the magistrate, described the offence as silly, mischievous and wicked.

GLASGOW TRAMWAYS.—The tramway cars of the Glasgow Corporation, which have been lighted for some time past by electricity, are now lighted with oil lamps, and a small committee has been appointed to consider and report as to the best method of lighting the cars. In commenting upon the subject of the electric lighting Mr. W. Paton, who moved the adoption of the Tramways Committee's minutes at the last meeting of the Corporation, said that there could be now no doubt that the Froggatt Electric Lighting Company (now in liquidation) had taken a contract which it was quite apparent they were unable to carry out. The contract had all through been very unsatisfactory, and the Committee were now in the position that for a time they must discard the electric light. They were extremely sorry to do this. Mr. Primrose strongly advised the Corporation to take over the lighting of the cars themselves, and Mr. Paton replied that this point was receiving attention.

HANLEY.—At the meeting of the Town Council on Tuesday, the Town Clerk reported the effect of the Potteries Extension Tramways Provisional Order, promoted by the North Staffordshire Tramways Company, which empowers the promoters to supply electrical energy for power only, for public and private purposes, and the General Purposes Committee recommend that representation be made to the Board of Trade objecting to the Company obtaining power to supply electrical energy for private purposes within the borough without the consent of the Council. A letter from Mr. Carruthers-Wain was read, stating that he had advised the insertion of a clause in the agreement providing for purchase by arbitration, instead of upon the terms of 5 per cent. reduction on the original cost. The letter also stated that the proposal in the Provisional Order empowering the promoters to supply electrical energy for private purposes did not apply to Hanley, but to the other towns in which the authorities did not provide electrical power. The Committee's recommendation was confirmed. The price of electric current

Digitized by Google

has been fixed at 6d. per unit up to a certain consumption; beyond this quantity 3d., and 4d. for places of worship, &c., requiring current on Sunday evenings only. Alterations were also made in the discounts allowed.

HYDE PARK (LONDON).—By order of the First Commissioner of Works, an electric arc light has been placed experimentally opposite the Marble Arch within Hyde Park. This step has been taken after consultation with the police authorities. Should the experiment prove a success, it is proposed to light with similar lamps the footpath between the Marble Arch and Albert Gate, a much-frequented route, and also to place another row round the band-stand, for use during the summer months. The *Daily Telegraph*, in making this announcement, says: "The public will give to this official intimation a cordial welcome. The electric light will not only add to the beauty of the park in the summer twilight, but will also materially alleviate the winter disadvantage of darkness, which often entails inconvenience on those who are compelled to traverse the park."

IPSWICH.—It has been decided by the Town Council to oppose the application of the County of London and Brush Provincial Company for an Electric Lighting Provisional Order, and to consult Prof. A. B. W. Kennedy on the subject generally.

KIRKCALDY.—At the meeting of the Town Council on Tuesday, on the motion of Councillor Hutchison, a Committee was appointed to make the necessary inquiries regarding the installation of the electric light at Kirkcaldy, and to report to the Council.

LAMBETH (LONDON).—Those members of the Vestry who were favourable to the supply of electric current being undertaken by the parish have been defeated, and we understand, the Vestry will now not oppose the application of the County of London and Brush Provincial Company for a Provisional Order, subject to certain conditions being inserted for the satisfaction of the Vestry.

LECTURES.—Prof. J. A. Fleming delivered an interesting lecture at the London Institution, Finsbury-square, E.C., yesterday, on "Experiments with Incandescent Lamps."—At the Polytechnic Society, Liverpool, on Monday, Prof. Hele-Shaw delivered a lecture on "The Hydro-Electric Installations at Niagara." The lecturer pointed out that so far back as 1885 no less than 10,000 H.P. was actually taken from the Falls for motive power purposes in the mills in the neighbourhood. The lecture was fully illustrated, and greatly interested a large gathering of members.

LLANDUDNO.—A discussion arose at the meeting of the District Council on Wednesday on a resolution to rescind a previous resolution of the Council on the subject of electric lighting, and empowering the Electric Lighting Committee to obtain a report on the subject from Messrs. Kincaid, Waller and Manville. It was now resolved that Mr. W. H. Preece be asked to report to the Council on the electric lighting subject generally, or, failing him, Dr. E. Hopkinson, whom failing, Messrs. Kincaid, Waller and Manville be asked to prepare a report.

LURGAN (IRELAND).—The Town Commissioners recently received a proposal from Mr. E. H. Walsh, an electrical engineer of Belfast, to light the main street electrically. It was proposed to erect 16 arcs between William-street and Queen-street. The cost of the plant is put at £478, and the annual cost of maintenance at £90. The matter has been referred to the Gas Committee.

NEWCASTLE-ON-TYNE.—At Wednesday's meeting of the City Council the report of the deputation which recently visited Bristol and Birmingham, in connection with the system to be adopted on the Newcastle tramways, was received. The Committee recommend that in order that the Council may be able, should it be decided to do so, to adopt electricity upon all or any of their tramways, application should be made to Parliament for additional provisions to be inserted in the Bill now before Parliament, which would include those sections of the tramways not now included to be worked by electricity; that in the meantime the matter be referred back to the Town Improvements Committee, to which additional members should be added, in order that the best means of working the entire system of tramways within the district should be considered and reported upon. A meeting of the ratepayers was announced to be held the next evening, and the Mayor recommended that, should it be decided to reject the report of the Committee, he should suggest that the Council's Tramways Bill be withdrawn. Mr. Alderman Winter, a member of the deputation, said they saw the overhead system at Bristol, and he would say at once that there could be nothing better. They were not sufficiently conversant with the working to come to a conclusion. The Tramway Company at Bristol seemed fully alive to their business; but he thought that if anyone would compare the streets of Newcastle with those of Bristol they would not hesitate to condemn the overhead system. On the contrary, Mr. J. Fitzgerald was of opinion that from what he had seen the electric trolley system, as applied at Bristol, would suit Newcastle admirably. Mr. T. Waller said that after his visit to Bristol and Birmingham he was convinced that the electric system was the best; and, more than that, it should be remembered that electrical engineering work was continually improving. Other members announced that they had come back converted, or confirmed in their preference for the cable system. Ultimately the report of the deputation was approved by 31 votes to 16. At the public meeting subsequently held, at which 2,000 were present, a resolution in favour of the Bill before Parliament with the proposed modification was lost, but a poll was demanded by a solicitor present, and this is to be taken. There are 36,647 voters on the municipal roll who will have an opportunity of declaring for or against the Corporation's scheme.

NESTON AND PARKGATE (CHESHIRE).—At the last meeting of the District Council the report of the Electric Lighting Sub-Committee stated that they had sent out 715 circulars, but only 110 had been returned. Seventy-eight were in favour of the electric light and 26 against, while six expressed no opinion. The Manchester, Sheffield and Lincolnshire Railway Company had countermanded the laying of gas mains to their new station at Neston, consenting to use oil lamps until the Council were in a position to supply current. A long discussion took place, but it was decided to postpone the consideration of the matter for six months.

NEWRY.—The Secretary of the Newry Chamber of Commerce announced at the last meeting that the undertaking of the Warrenpoint and Rosstrevor Tramway Company (whose head offices are in Belfast), was about to be taken over by an English company, who intend to extend the line to Kilkeel, to be worked by electric motive power. The name of the Edison-Swan Company was associated with this statement, but neither the London Edison-Swan Company nor the Manchester Company know anything of the matter.

NEWINGTON (LONDON).—A petition to the Board of Trade is being signed in strong opposition to the application made by the Newington Vestry for an Electric Lighting Provisional Order. The moving spirits are a body called the Newington and Walworth Ratepayers' Association. The grounds upon which objections are taken to the scheme are that the district is mainly composed of streets of small houses with few factories or manufacturing premises, and that the shops and business premises are comparatively small, and that, therefore, the demand for current is likely to be so small as to leave the lighting undertaking a charge upon the rates.

NEWPORT (MON.).—At the last meeting of the Town Council the Electric Light Committee recommended the borrowing of an additional sum of £12,000 for electric light extensions, &c. Alderman Moses, in moving the adoption of the report, spoke of the popularity of the light and of the steady increase in the demand for current. The report was adopted.

OLDHAM.—At the meeting of the Electric Lighting Committee of the Town Council last week a report from Prof. A. B. W. Kennedy was read in reference to the proposed extension of plant at the electric supply station. Prof. Kennedy recommends that the station should now be completed according to the original design. It will then be large enough to contain four additional dynamos, each capable of supplying current to 6,000 8 c.p. lamps at one time, bringing up the total to 28,000 8 c.p. lamps. This would enable the Committee to overcome arrears and to supply current for all probable demands for some time to come. The extensions are estimated to cost between £7,500 and £8,000. It was decided to adopt Prof. Kennedy's report, and he is to be asked to prepare a complete scheme.

OSWESTRY.—The General Purposes Committee have decided to ask the local electric light company to submit an estimate for the electric lighting of the Askew Roberts Memorial Clock.

PEMBROKE.—The gas contract for the town lighting terminates on July 1st next, and one ward of the town has asked the sanction of the Distric Council for powers to negotiate for the lighting of the town by electricity. An offer has been received from Mr. J. C. Howell, of Llanelly, to light the town electrically.

PERTH.—A Committee has been appointed to consider the question of lighting the Corporation Buildings, water power being used.

PLYMOUTH.—At Monday's meeting of the Town Council the report of the sub-committee appointed to visit several electrical stations was presented. It will be remembered that some time back Dr. J. A. Fleming presented an exhaustive report dealing with the subject of the lighting of the town by electricity, and this and other reports received by the Council are commended by the Committee. The Committee are unanimously favourable to the introduction of the electric light. Visits were made to Bristol, which gave the Committee an opportunity of inspecting the electric cars of the Tramway Company. The report contains an opinion to the effect that the Committee consider that the overhead system of electric traction, if care and attention be paid to design and form, and if the columns carrying the conductors are used as lamp-posts for arc lights, causes no disfigurement to the thoroughfares, and that the system is safe, convenient, clean and

Digitized by Google

economical. The Committee further state on the subject of traction that it is impossible to resist the conclusion that the Plymouth cars should be worked by electricity, for not only is the cost per car per mile less than half that at Plymouth, but the cars are of such size that a far greater number of passengers can be accommodated on every trip. "The saving in our tram lines would be enormous if the propelling power were electricity," say the Committee in their report. The City of London Station, St. Pancras, Brighton, Plymouth and Taunton were also visited. As a result of these visits the report concludes by recommending that the Town Council should itself put into force the powers it has obtained for supplying electricity within the borough; that the electric lighting should be combined with a dust destructor scheme, and that the supply station should be designed and equipped so that current for traction purposes can be supplied. It finally recommends that an engineer be appointed at a salary of £300 per annum, rising to £400, and that the Hoe and the principal places of public resort and the main thoroughfares should be lighted electrically forthwith.

PUBLIC LIGHTING IN THE CITY OF LONDON.—Mr. J. Cecil Bull, Manager and Secretary of the City of London Electric Lighting Company, points out in a letter to a contemporary that the charge by the City of London Electric Lighting Company for lighting the streets by electricity is only £26 per lamp per annum, which figures work out to barely 3d. per Board of Trade unit, "instead of the 5d. obtained by the more fortunate Vestry of St. Pancras."

RAWMARSH (YORKS).—The Sheffield and District Electric Tramway Company have offered the District Council £100 a year for the right of running through their district, and further undertake to keep the road in good repair a certain distance each side of the tramway. At the request of the Council the original terminus point has been extended.

RHYL.—The electric light has just been introduced into the works and premises of Messrs. Charles Jones and Sons, Foryd, Rhyl. The machinery has been supplied by Messrs. P. R. Jackson and Co., of Salford. Twenty-seven 16 c.p. incandescents and two 2,000 arcs are employed, while a special feature of the installation is a number of hand incandescent lamps, which can be used by the workmen at will. A complete telephonic installation has also been erected.

SOUTHAMPTON.—A meeting of the Electric Lighting Sub-committee is to be called for the purpose of taking into consideration the question of the purchase of the Southampton Electric Light and Power Company's undertaking.

SOUTHPORT.—From a statement by the borough accountant it would appear that the working of the electricity works for 1895 resulted in a loss of £210, which will, of course, soon be wiped off. There is a small unexpended balance upon the present borrowing powers of the Corporation, and application is to be made to the Local Government Board for power to borrow a further £4,000 to extend the mains to London-street and Chapel-street.

SOUTH STAFFORDSHIRE TRAMWAYS.—Mr. J. Noake, Mayor of Walsall, has succeeded in bringing about an arrangement between the Electric Construction Company and the South Staffordshire Tramways Company, under which the electric trams will continue running until March 27th next pending further negotiations.

STAFFORD.—Alderman Wormal presented the report of the Gas and Electricity Committee at last week's monthly meeting of the Town Council. The report states that the Committee have decided to modify the charges for electricity meter hire, and certain modifications of the discounts allowed on electric current accounts were also approved.

STAPLETON (BRISTOL).—The District Council have decided to oppose the application of the Great Western Electric Light and Power Company for a Provisional Order for this district.

ST. PANCRAS (LONDON).—On the recommendation of the Electricity Committee the Vestry have decided to supply current to places of worship at 3d. per unit.

SUNDERLAND.—The Highways Committee of the City Council now recommend that the electric supply station and plant be extended in accordance with the report of the Borough Electrical Engineer, and that steps be taken to borrow the necessary amount required for the work. Tenders are to be obtained for the proposed extension, subject to the Local Government Board's sanction. It will be remembered that opinions were divided as to whether steam or gas engines should be selected for the extensions; it has now been finally decided that steam engines shall be used.

SWANSEA.—The scheme prepared by Mr. Manville has now been submitted to Mr. W. H. Preece who will examine and report upon the matter generally to the Corporation. A Local Board enquiry into the Corporation's application to borrow £60,000 for electric lighting and dust destructor purposes is to be held on the 22nd inst., before Mr. W. M. Ducat.

TAUNTON.—The recommendation of the Finance Committee of the Town Council, that certain of the public electric lamps should be extinguished in the narrow thoroughfares of the town, and that no additional electric lamps should be placed in these thoroughfares, has been rejected.

TIGHNABRUAICH (ARGYLLSHIRE).—Mr. S. Millar, proprietor of the Tighnabruaich estate, has offered to put down the necessary plant for lighting the district electrically, on condition that the ratepayers pay the annual cost of maintenance, about £40. Mr. Millar's proposal provides for the erection of 25 lamps for lighting the road from the Post Office to Rhu Ban and the pier. A Committee has been formed to consider the proposal, and negotiate with Mr. Millar in the matter.

THEATRE LIGHTING.—A licence was granted by the Croydon County Council on Tuesday to the new Grand Theatre and Opera House, High-street, Croydon, which is to be lighted throughout by electricity.

TRAFALGAR SQUARE.—At last public attention is being directed to the wretched lighting of this noble space. A correspondent of a leading London daily paper points out that this, one of the finest spots in Europe, is the most wretchedly lighted of any of the metropolitan open spaces; and he suggests that powerful electric arc lights should be placed at convenient spots.

WALSALL.—The report of the Electric Lighting Committee of the Town Council on the subject of the electricity works was presented at the Monday's meeting, and states that the works have been carried out by the several contractors in a very satisfactory manner, and it is believed that the installation will be one of the most complete in the country. The price of current has been fixed at 6d. per unit for lighting and 4d. for motive power, less 2½ per cent. discount for monthly payments. A further £600 for an additional tranformer for the St. George's Hill sub-station was approved.

WATFORD.—It has been decided to appoint a Committee to consider the question of introducing the electric light for the public lighting of Watford and district.

WIGAN.—Some time ago the Town Council invited tenders for electric light plant. The Council have now decided to invite John Fowler and Co. (Leeds), the Corlett Electrical Engineering Co., Mather and Platt, the Brush Co., and Siemens Bros. and Co. to again tender on amended specifications.

"WORTHLESS ELECTRIC LAMPS."—Under this heading a long article appears in the *Daily Telegraph* of the 16th inst., from a correspondent who complains of "a deterioration in the quality of electric lamps, dating from the expiry of certain patents."

DINNER.—The employés of the Exchange Telegraph Company dined at Lake's Restaurant, Gracechurch-street, E.C., on Saturday last. Mr. Higgins presided.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended September 30th last, which will be presented to the forty-seventh half-yearly ordinary general meeting of proprietors to be held at Winchester House, Old Broad-street, London, on the 23rd inst., at one o'clock:—

The revenue for the period amounted to £409,779. 15s. 6d., from which are deducted £96,703. 19s. 7d. for the ordinary expenses and £47,165. 2s. 7d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £3,423. 4s. 7d. for depreciation of spare cable, £821. 2s. 3d. due to revaluation of currency assets, and £5,748. 15s. 5d. for income tax, there remains a balance of £255,917. 11s. 1d., to which is added £1,252. 3s. 9d. brought from the preceding half-year, making a total available balance of £257,169. 14s. 10d. From this balance there have been paid—

Interest on debentures and debenture stock	£27,520	11	8
Dividend on Preference shares	20,296	5	5
Two interim dividends of 2s. 6d. per share each on the Ordinary shares	100,000	0	0
	£147,816	17	1

After carrying £10,000 to the reserve fund for maintenance ships, and £50,000 to the general reserve fund, there remains a balance of £49,352. 17s. 9d., which is carried forward to the next account. The revenue includes £25,447. 14s. 2d., dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

Lord Sackville A. Cecil and Mr. George Garden Nicol retire by rotation, and offer themselves for re-election, as do the auditors, Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Welton, Jones and Co.

Direct United States Cable Company (Limited).

The report of the Directors of this Company for the six months ended December 31st last, to be presented at the thirty-seventh ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Tuesday, the 21st inst., at 2 o'clock, states that the half-year's revenue, after deducting out-payments, amounted to £43,938. 9s. 4d., as compared with £38,342. 8s. 4d. for the corresponding period of 1894, being £5,596. 1s. in favour of the half-year under review. The working and other expenses for the same period, including income tax, but exclusive of cost of repairs of cables, amounted to £19,057. 15s. 9d., leaving a balance of £24,880. 13s. 7d. as the net profit, making, with £1,410. 0s. 9d. brought forward from the previous half-year, a total of £26,290. 14s. 4d. For the corresponding period of 1894 the working expenses and other payments amounted to £19,024. 6s. 3d. Interim dividends of 2s. per share for the quarter ended September 30th, and of 2s. for the December 31st quarter (payable January 24th), amounting to £12,142, have been declared, and, after setting aside £10,000 to the reserve fund account, the balance of £4,148. 14s. 4d. on the revenue account has been carried forward.

During the half-year repairs of the Company's cables, including provision to December 31st for operations not yet fully completed, have cost £6,984. 14s. 6d., which has been debited to the reserve fund account as heretofore, the balance of which, with the addition of interest and the amount set aside from revenue account, now amounts to £306,005. 1s. 4d.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "The Electrician" Electrical Trades' Directory and Handbook, 1895, pages *304-332, &c., &c.*

WILLIAM SOUTTER AND SONS (LIMITED).—This Company was registered on January 8th, with a nominal capital of £25,000, in 1,750 Ordinary and 750 Preference shares of £10 each, to acquire and take over the business carried on by William Soutter and Edwin Soutter, under the style of "William Soutter and Sons," at Hockley, Birmingham, and Holborn Viaduct, London, and to carry on the business of manufacturers of and dealers in every kind of art metal work, chandeliers, electric light fittings, metal founders, electro-platers, electricians, electrical engineers, &c.

ECONOMIC ELECTRIC SPECIALITY COMPANY (LIMITED).—The annual return to January 3rd has been filed. The whole nominal capital of £50,000, in £1 shares, has been taken up, and 49,993 have been issued as fully paid. The full amount has been called on the remainder, and £4 has been paid.

ELECTRIC FITTINGS, HIRING AND MAINTENANCE COMPANY (LIMITED).—The annual return to December 2nd has been filed. Only seven shares have been subscribed for out of a capital of £200,500, divided into 40,000 shares of £5 each, and 500 shares of £1 each, and no calls have as yet been made.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return to December 6th has been filed. The capital of £15,000 is divided into 14,950 Ordinary and 50 Founders' shares of £1 each; 6,709 Ordinary and all the Founders' shares have been taken up, and 761 Ordinary have been issued as fully paid. The full amount has been called upon the remainder, resulting in the receipt of £6,009. 15s.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30⅞d. per oz. (Jan. 16th). Consols (2¾ per cent.) 107⅝—107⅞ for money, 107⅝—107⅞ for account; 2¾ per cent. 104¼—104⅜ (Jan. 16th). Stock Exchange Settling Days: Consols, Feb. 3rd; Stocks and Shares Continuation Day, Jan. 28th; Ticket Day, Jan. 29th; Pay Day, Jan. 30th.

BABCOCK AND WILCOX (LIMITED).—An interim dividend for the six months ended December 31st last at the rate of 6 per cent. per annum on Preference shares and 10 per cent. per annum on Ordinary shares, payable on February 12th, has been declared.

CITY AND SOUTH LONDON RAILWAY COMPANY.—The accounts of this Company for the half-year ended December 31st show a balance, after providing for debenture interest and the full dividend on the Five per Cent. Preference shares, sufficient to allow the payment of a dividend on the Consolidated Ordinary stock at the rate of 1¼ per cent. per annum, carrying forward a balance of £1,220 to the new account. The dividend is the same as for the corresponding period last year, £950 being then carried forward. The traffic returns of the Company for the week ended January 12th were £1,020, against £1,001 in the corresponding period of 1895, an increase of £19. The total receipts for the half-year amount to £2,037, against £2,004 in the corresponding period of 1895, an increase of £33.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company gives notice that the Transvaal Government have notified that they will now accept messages in code language.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 12th inst. amounted to £1,120. The amount for the corresponding week last year was £866; increase, £254.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY (LIMITED).—The Directors of this Company have declared a dividend at the rate of 5 per cent. per annum for the half-year ended December 31st last, making 4½ per cent. for the year. At the eighth ordinary general meeting of the shareholders of the Company on Tuesday the Chairman (Mr. Alderman Gibson), in moving the adoption of the report and accounts, referred to the great increase in the demand for electric current during the past year, and stated that they had sold 48,000 units more than in 1894. The report and accounts were adopted.

STOCK EXCHANGE.—The following shares have been ordered to be quoted in the Official List: City and South London Railway, further issue of 469 Five per Cent. Perpetual Preference Shares, Nos. 7,651 to 8,119.

WATERLOO AND CITY RAILWAY COMPANY.—The fourth half-yearly general meeting of the shareholders of this Company will be held at Waterloo Station, London, on Thursday, February 6th, at two o'clock. A special general meeting will follow for the purpose of considering the provisions of a Bill introduced into Parliament, intituled "A Bill to confer further powers on the Baker-street and Waterloo Railway Company." Extension of time for the completion of the line is asked for. The Bill will be submitted for the approval of the shareholders. The transfer books of shares will be closed from the 23rd inst. until the end of the meetings.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended January 10th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,664.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 923. [Vol. No. 13. XXXVI.] FRIDAY, JANUARY 24, 1896. PRICE SIXPENCE.

NOTES.

We publish in the present issue a full translation of Prof. Röntgen's recent communication to the Würzburg Physical Society on "A New Form of Radiation," and a brief abstract of a lengthy and most important Paper by Jaumann, appearing in the current number of *Wiedemann's Annalen* under the striking title of "Longitudinal Light." Röntgen, it will be seen, sums up strongly in favour of the theory that his X-rays are not merely a very ultra-violet radiation, so to speak, but are *longitudinal* vibrations in the ether. Jaumann shows that by assuming μ and k to be variable longitudinal vibrations follow on from Maxwell's equations, and that such vibrations account for many obscure phenomena connected with cathode rays of the Lenard variety and with the discharge by light of electrostatically-charged bodies. In other words, Röntgen, Lenard and others would appear to have discovered what Prof. Silvanus Thompson has, with characteristic preference for the picturesque, termed "ultra-violet *Sound*."

It may not be without interest at the present moment to recall the main points of difference and of similarity between Röntgen rays and Lenard rays—to use two brief and convenient expressions. Röntgen rays are *not* deflected by a magnet; Lenard rays are. Röntgen rays suffer far less absorption and diffusion than Lenard rays. Lenard found that his cathode rays failed to pass through anything but the thinnest soap films, glass, and aluminium foil, &c.; the Röntgen variety will traverse several centimetres of wood and several millimetres of metal or glass. Röntgen was able to take "shadowgraphs" and detect fluorescence 200cm. away from the discharge tube; 6cm. or 8cm. were enough to wipe out Lenard rays in air at atmospheric pressure, and even in hydrogen gas, at only 0·0164mm. pressure, the "radiation length" for cathode rays was only 130cm.; hydrogen at atmospheric pressure behaving as a decidedly turbid medium. These are, however, rather differences in degree than in kind. Lenard rays emanate, of course, from the cathode itself; but Röntgen rays, according to their discoverer, start from the luminescent spot on the glass wall of the discharge tube, at which the cathode rays terminate. The points of similarity between Röntgen and Lenard rays are their photographic activity, their rectilinear propagation (as evidenced by the sharp shadows cast) and the fact that in both cases it would seem the total mass of molecules contained in unit volume of any substance practically determines its transparency. All things tend to show that we are on the verge of a great scientific discovery, which may oblige us, *nolens volens*, to "rearrange our ideas."

The Berrenberg mechanical vacuum pump, described in another column, seems to us to be about as perfect as such a machine can be. How far a first-rate vacuum is necessary for commercial glow lamps, it is difficult to say; but if the exhaustion of an oil-flooded pump will do, we think the Berrenberg will give as good a vacuum as any. It will be inferred from this that we do not think it will give as good a vacuum as the mercury pump, Prof. Ayrton's tests notwithstanding. Such a pump cannot go beyond the vapour pressure of the lighter constituents of the oil used. The tests made were evidently not those of one well acquainted with the very crooked ways of lamp vacua. The McLeod gauge is notoriously untrustworthy, even on a mercury pump, and is also quite useless in dealing with low-pressure oil and water vapours. The method of opening lamps under mercury is generally unreliable, even as a comparison of the vacua of ordinary lamps; as a comparison of a bulb exhausted as Prof. Ayrton exhausted it and a commercial lamp, it is not less so. The principle of flooding an ordinary pump with oil or glycerine to avoid clearance is quite old in sugar works and glow lamp manufacture. So is exhausting with delivery into another exhausted chamber. As a sealing medium for preventing leaks in piping, oil is not to be recommended. Metal is impervious to air, and the vacuum that can be preserved in a system of gas piping is limited only by the pressure of the vapour of the liquids used in the redlead. Greased stopper joints were tried in the early days of lamp making, but were discarded, though their rejection may have been due to too high an ideal. The cost of pumping lamps is not the serious item that many inventors of queer pumps imagine. If a philanthropic inventor came round and exhausted lamps for nothing, it would make little or no perceptible difference in the price of the lamps. To exhaust lamps well is far more important than to do them cheaply.

The spectacle of an electrical industry clamouring for an increase in permissible supply pressures, and then turning shyly from using them when they have been granted, must be a somewhat amusing one for the Board of Trade, presuming, of course, that this much-worried Department is capable of being

Digitized by Google

amused. Nevertheless, there may be some practical utility in having the right to use 250 volts, whilst recognising the fact that this use must only be cautiously made. In his recent Presidential Address to the Northern Society of Electrical Engineers, Mr. W. P. J. Fawcus repeats the warning which already has often been made, in regard to the injuries both to the consumer and, ultimately, to the electrical industry, which may arise from the introduction of a pressure of 250 volts into a consumer's premises. "It would be an evil day for the industry," he remarks, "if through the occurrence of fatal accidents to the general public the electric light should again get the name of being dangerous, which fortunately it has now practically lived down." As we recently observed, however, it is not so much fatal accidents that are to be feared, as the minor inconveniences of harmless but unpleasant shocks.

A kindred topic, that of the incandescent lamps for the higher pressure service, is also touched upon by Mr. Fawcus; and it is of interest to compare his remarks with a short communication from a correspondent which we publish this week in our Notes column. Judging by our correspondent's experience, makers do not find it particularly easy to produce lamps, even at 100 volts, which shall comply with specification in regard to efficiency, candle-power, and voltage. What, then, may be expected if a general conversion to 200-volt lamps is to take place? Mr. Fawcus advocates multi-filament lamps in this latter case; but we believe it is generally considered that the compound filament is only a temporary and makeshift contrivance, and that a really successful high-pressure lamp will have to consist of a suitably strong single filament. The cheapening of lamps must inevitably tend to their being run at a higher rate, and therefore at a reduced life. This can only be fairly styled "over-running" when the candle-power of the lamp at the marked voltage is in excess of the marked candle-power. There is no known process by which a carbon filament can be worked at 2½ or 3 watts per candle-power instead of at 4 watts, except it be by running it at a higher temperature; and it ought to be understood by everyone who does so that in our present state of knowledge this will apparently have to be done at a sacrifice of what has up to now been deemed normal lamp-life and normal constancy of candle-power. But, if 200 volt 2½ watt lamps are to replace the old 100 volt 4 watt lamps in practice, it will be all the more necessary that the marked voltage shall not develop more than the correct temperature in the filament, since the lamp, already severely stressed, will be liable to double the fluctuation of pressure that occurs in the present 100-volt systems. Not only, that is to say, will the lamp normally be run much nearer to its fatal point, but it will have to withstand very much greater abnormal encroachments on its slender margin of safety. To meet these more stringent conditions lamp makers will have to subject their stock to much closer supervision and more careful selection than would seem to be the case in this era of cheap lamps.

On Thursday evening last week Dr. John Hopkinson prefaced his Inaugural Address by an appeal to the members of the Institution of Electrical Engineers to do something in their corporate capacity towards the defence of the country. Some people, Bacon tells us, "in all deliberations find ease to be of the negative side and affect a credit to object and foretell difficulties;" and we have no wish to join that noble army. Nevertheless, whilst we are in cordial agreement with the Presidential exhortation to each member to do his duty according to his opportunities, it may be permissible to doubt whether the spectacle of the Institution of Electrical Engineers precipitately converting itself into a submarine-mining or search-light corps will be altogether impressive. It is, as the President truly remarked, the duty of everyone to consider what he can personally contribute towards the nation's defence, and if the Committee appointed by the Council succeed in disabusing members of the Institution of the idea, that in contributing, with the usual quantum of grumbling, to the revenue of the country, they have completely fulfilled their duty towards it, the Committee will not have been called together in vain. Technical training is cheerfully submitted to in order to gain a livelihood; it would be well if a little military training were equally cheerfully submitted to by our young able-bodied electrical engineers, in order that they may prove of at least unit use in time of need.

Men much over 30 who have not taken the trouble to gain the preliminary insight into military technics afforded by a few years volunteering or its equivalent, are not likely, however great their patriotic ardour in a moment of panic, to become "efficient" in time to be of any use. Their patriotism and good sense, it seems to us, would be better evinced by encouraging every young fellow they know to do that which they themselves have left undone. It is only by quiet and *timely* voluntary military training that conscription will in the long run be avoided. Should that dread Continental invention ever reach these shores, together with the many other imported evils "made in Germany," it is some consolation to learn on unimpeachable authority that conscription, even, is not without its compensations. The too-close attention to the fact that it takes the workman away from his work for two or three years at the most economically valuable period of his life has made many overlook both the life-long physical gain derived from spending those very years in healthy outdoor exercise, and the moral gain due to the formation of disciplined habits. Common sense might have divined the existence of this compensation, but, as usual, the dead-weight of authority has been sufficient to prevent most people from thinking the matter out for themselves. The following quotation from the Report of a delegation of employers and employees representing the iron and steel industries of Great Britain, which recently visited the Continent, is a testimony to the compensating influences of a brief period of military training. The italics are our own:—

"One of the most admirable features of the administration and operation of the iron and steel works that we visited on the Continent, almost without exception, was *the splendid discipline maintained. The workmen generally discharged their duties as if they were acting under military commands. There was no slovenliness, no undue haste, no noise, no idling about, and the foremen, in a quiet and unobtrusive manner, appeared to*

Digitized by Google

control everything without commotion. Each man worked as if he were a piece of machinery fitted into its proper place, which did exactly the right thing at the right moment, because it could not do otherwise. The operations, as a rule, were carried on with the regularity of clockwork. We are also bound to acknowledge that we were greatly struck with *the splendid physique* of the men employed in the works that were visited in Germany, and not less so with their sobriety, their steadiness, and their readiness to act on instructions. These qualities are manifestly of much value alike to employers and employed. The workman who is regularly and steadily engaged at work is not only earning better wages for himself, but is in a better position to do good work, while the effect of such a state of matters on the employer is that he gets the maximum production out of his plant, no heats being lost through broken time, &c. *The early military training of the workman has probably a good deal to do with this system of working;* but, whatever its cause, its effect on the industry of the country is very important."

Owing to the great extension of the metropolitan electric light mains during 1895 we have been obliged to correspondingly increase the area covered by our annual map, the 1896 edition of which is published with the present issue. St. Pancras has sent a long bifurcating feeler northwards; the streets of Hampstead have become green, not with grass, but with mains; a similar fate has befallen Clerkenwell, and the Islington station has sent a long, lonely line to the north and another to the south. Next year, when we hope to include the Wandsworth district of the County of London and Brush Provincial Electric Lighting Company, the size of the map will be still more portentous. We have to thank the engineers of the various electric supply concerns for their kind assistance in bringing our map accurately up to date.

The Institution of Junior Engineers.—The eleventh anniversary dinner of this Institution takes place on Saturday at the Westminster Palace Hotel, the President (Mr. Archibald Denny) in the chair.

Appointment.—The appointment of Scientific Adviser to the Trinity House, which has been in abeyance since the resignation of Prof. Tyndall, and which was formerly held by Faraday, has been revived, and has been accepted by Lord Rayleigh.

Northern Society of Electrical Engineers.—Mr. W. P. J. Fawcus, Managing Director of the Manchester Edison-Swan Company, has been elected to the office of President of this Society for 1896, the Vice-Presidents being Messrs. S. Z. de Ferranti and C. M. Dorman (of Dorman and Smith). The hon. treasurer is Mr. Eckstein, of the Manchester branch of the General Electric Company, and Mr. J. Vincent Swindells remains hon. secretary.

The Smithsonian Institution.—In the last number of *Nature* there is commenced an interesting series of articles on the Smithsonian Institution, of Washington, with a historical sketch of the Institution and its founder. The first article is illustrated with a picture of the Smithsonian buildings and portraits of Joseph Henry, S. P. Langley, Chief Justice Fuller and S. F. Baird, who are, or have been at one time, officially connected with the Institution.

Cable Interruptions and Repairs :—

	Date of Interruption.	Date of Repair.
Puerto Plata—Martinique ...	December 19, 1895 ...	—
Perim—Obock	January 2, 1896 ...	—
Bathurst—Sierra Leone	January 14, 1896 ...	January 14, 1896
Konakry—Sierra Leone	January 14, 1896 ...	January 18, 1896
St. Thome—Loanda	January 15, 1896	—
Odessa—Constantinople	January 17, 1896 ...	—
Durban—Lourenco Marques..	January 19, 1896 ...	January 22, 1896

A Contradiction.—We are given to understand that nothing is known at the General Post Office of the proposed telephone trunk line between London and Berlin, which the papers state Dr. Stephan alluded to a day or two ago in the Reichstag in connection with the German Post Office estimates. Dr. Stephan was probably alluding to the proposed new Anglo-German *telegraph* cable.

An Old Friend in a New Office.—"It is rather amusing to gas engineers," says the *Journal of Gas Lighting*, "to observe that their good friends the electric lighting engineers are just now having their turn at towns' refuse utilisation. Time was when this same rubbish, with and without the admixture of sewage or sewage sludge, was highly recommended as good stuff for making illuminating gas from. Indeed, it is hard to say what the same kind of material has not been said to be good for, at one time or another, by various perfervid individuals who fancied it ought to be made useful somehow."

Coventry.—A serious accident took place in Bishop-street, which is a very steep decline, on Wednesday afternoon. One of the electric cars was proceeding from Foleshill to Coventry, when, at the top of Bishop-street, the brake refused to act, and in consequence the tram attained a speed of about 25 miles an hour. Near the bottom of the street, on the line, stood a lorry with a stage on top used in connection with the repair of the trolley wire, on the top of which, 20ft. above the ground, a man was working. The car collided with the trolley, and the man was pitched into the roadway and severely injured.

Cable Communication with South Africa.—In explanation of the recent rapid repair of the Delagoa Bay—Durban cable, it may be mentioned that the Eastern and South African Company, in view of the exceptional importance at the present time of maintaining communication with South Africa, ordered the cable steamer "Great Northern," then stationed at Cape Town, to proceed to the East Coast, calling on the way at each port where the lines connect. The day after the ship's arrival at Delagoa Bay the cable thence to Durban broke, and, as the fault was only 27 miles distant, the ship was able promptly to effect the repair.

Dundee.—On Tuesday an unfortunate breakdown occurred in connection with the Dundee electric light supply, as a result of which a number of shops in the city had to be closed. It seems that the steam feed pipe of the pumping engines fractured, and recourse had to be had to an injector. This arrangement worked smoothly till the afternoon, when a valve gave way, and as the supply of water to the boilers could not be kept up the fires had to be drawn. From the fact that there were 10,000 lamps in circuit at the time, recourse could not be had to the batteries, which are only capable of supplying about 1,500 lamps.

Obituary.—On January 1st Mr. Alfred E. Beach, proprietor and editor of the *Scientific American*, died of pneumonia. He was born in 1826 in Springfield, Mass. In 1846 he and his former schoolmate, Mr. Orson D. Munn, founded the firm of Munn and Co., and became the proprietors of the *Scientific American*, which at that time was the only weekly journal of its kind published in America. For nearly 50 years Mr. Beach was active in the editorship of the paper and in the direction of the extensive patent business of the firm. Mr. Beach has made several inventions.——We regret to record the death on Wednesday of Sir Henry Calcraft, K.C.B., Permanent Secretary to the Board of Trade from 1886 to 1893.

Waterfalls and Aluminium Works.—A Reuter telegram from Christiania states: The estate of Hafslund, near the great waterfall known as the Sarpsfos, between here and Göteborg, has been acquired by a syndicate, consisting chiefly of German and American capitalists, for the sum of 800,000 kroner. The purchasers intend to form a large company to electrically utilise the power of the falls and establish aluminium works. The Sarpsfos is one of the finest falls in south-eastern Norway, being 74ft. in height and 116ft. in width. The water is, however, already utilised by numerous saw mills and cellulose factories, and the railway crosses the fall, so that the proposed new works will probably not interfere to any great extent with the picturesque aspect of the place.

Expiring Patents.—Next Sunday, the 26th inst., will expire Patent No. 386 of 1882, granted to W. T. Henley for "Improvements in the Construction of Cores for Sending Electric Currents for Telephone, Telegraph and other Purposes, and in Apparatus connected therewith." One of the two claims is for: "The construction and employment of cores for cables

Digitized by Google

with multiplec onductors substantially as set forth."——On Friday next, the 31st inst., will expire patent No. 489 of 1882, granted to G. Skrivanoff for "Improvements in Electrical Batteries for Telegraphic, Telephonic and other Purposes." There are four claims, dealing with a battery composed of a Zn C couple, with electrolytes and depolarisers of chloromercurate of ammonium and chloride of sodium, and with interposed layers of filtering paper or asbestos soaked in chloride of zinc and chloride of sodium, with or without glycerine.

Fatal Accident at the Hampstead Electric Supply Station.—On Tuesday evening last Edward Clarkson, a jointer in the service of Messrs. Siemens Bros., proceeded without anyone's orders to the back of the switchboard at the Hampstead Vestry's electric supply station to disconnect an alternator, which had just been tested, from a water resistance and reconnect it up to the station "bus" bars. A heavy fall was heard, and on going into the spacious well-lighted alley at the back of the board one of the assistant-engineers at the station found Clarkson dead on the floor. He had evidently come in contact with a minute piece of bare wire belonging to a voltmeter connected to the "bus" bars with one hand, and not knowing this, proceeded to connect up the alternator, and the insulation of the connection being faulty, and the man unprovided with gloves, he short-circuited the station "bus" bars from one hand to the other.

Anderson Closed-Conduit System at Leeds.—A short experimental line on the Anderson closed-conduit system has been laid down at Hunslet, near Leeds. In this system the motors in the cars are fed from an underground conduit. Along the track, 21ft. apart from each other, are iron boxes, the lids of which are level with the road. In each box are three pins, about 1in. in diameter. These pins are made to rise about 3in. above the road as the car passes along the track. These small projections convey the current from the conduit to a collecting bar at the bottom of the car. At the end of the collecting bar is a ramp, and as the car passes over, the ramp knocks down the pins to the level of the road, and the current from that particular box is at once automatically switched off. The knocking down of these pins sends up the pins in the next box, which is then under the collecting bar right in front of the car. The estimated cost of constructing this conduit system is £1,200 per mile.

Röntgen Rays.—Prof. Röntgen's discovery with regard to radiations from a Geissler tube has been put to practical use in Vienna by Prof. Mosetig, whose experiments on two patients on whom operations were to be performed were attended with complete success. The "shadowgraphs" taken showed with the greatest clearness and precision the injuries caused by a revolver shot in the left hand of a man, and the position of the small projectile. In the other case, that of a girl, the position and nature of a malformation in the left foot were ascertained. The experiments are regarded as affording a means of determining the exact spot where an operation may be necessary. Mr. A. A. C. Campbell Swinton, whose "shadowgraphs" caused much interest at the Camera Club and at the Institution of Electrical Engineers last Thursday week, finds that no effects are evident when an induction coil is employed in the ordinary manner. He used an alternating current to work a coil, the secondary of which charged a battery of Leyden jars, the discharge from these being passed into a second Tesla induction coil. Prof. Silvanus Thompson has, we believe, discovered that Röntgen rays are also generated in the electric arc, and has succeeded in getting an excellent "shadowgraph."

Street Lighting at Munich.—On Sunday, December 22nd, 1895, the new street-lighting plant was handed over for ordinary working. Up to the present there have been two generating stations, with water and steam power, supplying 66 5-ampere and 210 10-ampere arc lamps, the distribution being on the three-wire system, 6 lamps being always in series between outer and middle wire. The arrangement was such that the lamps on one side of the three-wire system were switched off at midnight, while the others burned through the whole night. The extension was carried out on the lines proposed by the municipal electrical engineer, Herr Uppenborn, by which 12 lamps are put in series across the outers of the former three-wire system, the middle wire being omitted altogether. The extension plant consists of two 250 H.P. turbines, each driving two Schuckert dynamos. A steam plant of two 350 H.P. engines has also been provided for further extension and as a stand-by. Provisions are also made for an additional 700 H.P. and a 1,000 H.P. engine. The work in connection with the underground mains has been enormous; 95 miles of cables have been laid in 25 miles of trench, Munich, it must be remembered, being a town which covers a large area. The extension comprises 480 10-ampere and 48 5-ampere arc lamps. The lamp-posts are of various designs, from very ornamental patterns for the principal streets and squares to plain posts in side streets. Switch pillars are erected about the town, from which the different circuits can be cut in and cut out. The whole plant now comprises 690 10-ampere and 114 5-ampere arc lamps.

Association of Technical Institutions.—The report of the Council of this Institution, which is to be presented at the annual meeting, to be held at the Goldsmiths' Hall, to-day, states that since the issue of the last report a number of additional institutions have been admitted to the Association during the year. Suggestions have been made to the Committee of Her Majesty's Privy Council on Education with the view to modification of the basis for the calculation of the Government grant for technical education purposes. A Committee was appointed to consider the question of examinations in practical chemistry, the result of whose labour was the submission of resolutions to the Department of Science and Art in regard to certain modifications of the technical education code. The Council recommend the meeting to authorise them to make representations to the Science and Art Department on the inadequacy of the present grants to science and art classes, and to make urgent representations to the Privy Council Committee on Education requesting that clauses may be inserted in any Bill which is based on the report of the Royal Commission on Secondary Education recently issued in order to secure that the continued efficiency of technical institutions shall not be impaired by any diminution in the amount of aid which they at present receive from votes available under existing Acts of Parliament and in the form of grants from the Science and Art Department. The President for 1896, and vacancies in the Council, are to be elected at the meeting. The Right Hon. A. J. Mundella, M.P., is the Council's recommendation for the presidency.

The Cheltenham Fatality.—The Board of Trade inquiry into the circumstances attending the recent death of John Pugh, employed as jointer in the Electric Light Department of the Cheltenham Corporation, was held at the Municipal Offices on Wednesday last week, before Major Cardew.—Mr. M. Hamilton Kilgour, Borough Electrical Engineer, gave it as his opinion that no protective covering to metal traversed by high-pressure currents would really reduce the danger. In most cases covering would reduce the danger at the start, but it might ultimately increase it, owing to the freedom in handling which it would cause.—The Inspector thought that the question in this and other cases is whether there has not been a tendency to leave too much of this highly-charged metal exposed, instead of having insulating covering for it.—Replying to the Town Clerk, Major Cardew said the carelessness of workmen in handling charged metal, and particularly in touching instruments in connection with the high-pressure system, was incredible.—Mr. R. Cresswell, surgeon, who attended the deceased in the transforming chamber, adhered to his statement before the coroner that the position in which the deceased was working was a very dangerous one.—Mr. Kilgour was re-called, and asked by Major Cardew whether he considered it absolutely necessary that the high pressure should have been kept on during the time the men were working in the sub-station. He replied: It would have meant switching off the supply from a part of the town if the high pressure had been taken off. There was no work being done on the high-pressure side on this occasion.—This accident occurred shortly after eleven o'clock in the morning, and in the middle of the day no great inconvenience would be caused by switching off. There were one or two customers who used the light all day.

Glow-Lamps.—A Correspondent, who has had much commercial experience of cheap glow-lamps in this country, writes to the following effect in answer to an inquiry we made:—The tests of incandescent lamps which I began some time ago were carried out to find which was the best 3-watts-per-candle-power lamp in the market, as I consider a lamp of that efficiency to be the best all-round lamp for general use, especially where some consumers wish to make an economy over their previous consumption of current with the usual 4—5 watt lamp. *There was great difficulty in getting lamps anywhere near the right efficiency even when the makers were paid an extra price per lamp for specially picked lamps.* Following this I give some of the readings taken on lamps submitted for trial. They are of both English and Continental manufacture:—

	Nominal c.p.	Actual c.p.	Watts per c.p.
Ediswan	16	21	2·3
	16	18·5	2·6
	16	19·75	2·45
	8	7·6	3·1
These lamps were much over-run at the marked voltage (=100 volts).			
Robertson	32	23·8	3·95
	32	23·6	3·12
	32	26·6	3·57
Sunbeam	32	29·0	3·9
	16	12·7	4·3
	10	8·5	4·7
Daylight	16	21·7	2·88
	16	21·0	2·72
	32	36·3	2·95
	32	30·8	3·38
	50	65·1	2·7
	50	60·4	2·86
Cruto	16	17·2	3·16
	16	14·8	3·8
Venus	16	12·2	3·3
	16	4·8	7·2
(After 100 hours burning.)			
Quanonne	8	8·0	4·1
	16	16·2	3·25
	25	20·5	3·0
	32	32·7	3·0

The above figures have been selected out of numbers of tests made on each type of lamp, and represent the average results obtained. I found that the makers generally selected the lamps by the total watts consumed, as, for instance, 48-50 watts for a 16 c.p. lamp, but regardless of the candle-power given by the lamp, and that most so-called high-efficiency lamps were simply ordinary lamps over-run at the marked voltage, and these lamps, if run at the nominal candle-power by reducing the voltage, were not better than an ordinary 4-5 watt lamp.

The Alternate-Current Transformer.—On Monday evening last Dr. Fleming delivered the first of his course of four Cantor lectures on this subject. The transformer, he said, existed in a three-fold character—there was the mathematician's transformer, clothed in an elaborate mathematical raiment; the contractor's transformer, of exceedingly high efficiency; and the real transformer, having its vices as well as virtues. The importance of considering how to reduce transformer-core loss was evident when one remembered that the energy consumed annually in the cores of all the transformers connected to the mains of the 47 alternating electric supply concerns operating 1,100,000 8 c.p. lamps in the United Kingdom amounted at least to about 1,600,000 kilowatt-hours, costing quite £6,000 per annum for coal alone. Transformers, the lecturer said, could be broadly classified as follows: (*a*) Iron core, (*b*) air core, (*c*) closed circuit, (*d*) open circuit, (*e*) constant current, (*f*) constant potential, (*g*) step up, (*h*) step down. Various methods of delineating alternating-current curves were then described, and, amongst others, the method fully described by the lecturer in *The Electrician* of February 15, 1895. The uses of polar curves and the meaning and significance of the "form factor" of the wave of an alternator (see *The Electrician*, May 10, 1895, and January 10, 1896) were then discussed. Reproductions in the form of lantern slides of alternating-current curves taken at Bankside station (see *The Electrician*, February 22, 1895) were then thrown on the screen, and the comparative stability of the P.D. wave form of the Mordey alternator strikingly shown, as well as the extreme peakiness of the Thomson-Houston curve (maximum value 3,500 volts) when the alternator is running on an inductive load. The harmonic analysis of alternator curves was then gone into, and it was stated that in practice it was found that every alternating-current curve could be synthesised by means of three simple sine curves suitably placed having frequencies of 1, 3 and 5 respectively. Dr. Fleming stated that it was an entire misconception to talk of transformers as "wiping out ripples" in the curve of primary E.M.F.—the secondary P.D. wave was an exact copy to a reduced scale of the primary. The interesting question of the influence of wave from on core losses was then gone into at some length, also the algebraical and geometrical construction of hysteresis curves from the P.D. curves. The lecture concluded with a reference to the essential connection of the "secondary drop" with wave form; with peaky P.D. curves drop is greater than with flat P.D. curves. At the end of the lecture an instructive exhibition was given of the capabilities of Dr. Fleming's wave-tracing motor in analysing the fluctuations in the light and temperature of an alternating-current arc (see *The Electrician*, December 20, 1895), the perfect synchronism of the motor with the fluctuations of current being made evident by the absolute steadiness of the image of the alternating arc in one particular phase projected on to the screen when the light of the arc was sent through a slot cut in an aluminium disc attached to motor axle.

The Pacific Cable Scheme.—Under date Sydney, January 19th, Reuter cables as follows:—An intercolonial conference of Postmasters-General concerning the appointment of Australasian representatives on the Pacific Cable Commission to be held in London, and for other matters, met here on Friday and yesterday. The Postmasters present were Mr. Joseph Cook, New South Wales; Mr. J. G. Duffy, Victoria; Mr. A. J. Thynne, Queensland; Dr. Cockburn, South Australia; and Mr. W. P. Reeves, the new Agent-General in London for New Zealand. Dr. Cockburn also represented West Australia and Tasmania. Mr. Cook took the chair. The following resolutions were adopted, subject to the approval of the various colonial Governments, and recommended to the Australasian Commissioners: "(1) That the Pacific cable should be constructed and owned jointly by the various Governments interested. (2) That the landing places of such cable should be only upon territory belonging to or under the control of the British Empire. (3) That the construction, working and maintenance be borne by Great Britain, the Dominion of Canada, and the contributing Australasian colonies, in the proportion of one-third. (4) That the route from Fiji to Australia be to Norfolk Island, and thence bifurcating to the nearest convenient landing places in North New Zealand and Moreton Bay respectively. (5) That it is highly desirable that South Australia should join the other colonies in the Pacific cable project, and, having regard to their vested interests in the trans-continental line, Dr. Cockburn be invited to move a proposition embodying the terms upon which the South Australian Government would be prepared to join the other colonies." Upon this Dr. Cockburn submitted the following offer: "South Australia is willing to join in the project provided that a guarantee, either from the contributing colonies, or jointly with the Imperial Government, be given that the financial position of South Australia as regards the Port Darwin line be maintained on the basis of the average for the last five years." (6) That the colonies joining should contribute equally to the undertaking. (7) That in consideration of South Australia joining with the other contributing colonies in the project they would be willing jointly with Great Britain to guarantee that colony against a further loss in connection with their trans-continental line in consequence of the construction of the cable. (8) That Sir Saul Samuel and Mr. Duncan Gillies should be nominated as representatives of the Australasian colonies on the Commission in connection with the Pacific cable, and that they should be requested to consult on all important points with the Agents-General of the Australasian colonies." Under the same date the Melbourne correspondent of *The Times* cables: "Mr. Reeves and Dr. Cockburn strongly protested at Sydney against equal payments by the colonies for the cost of the maintenance of the Pacific cable. They declined voting on the question and wished the payments to be on the basis of population."

ELECTROMAGNETIC THEORY.—LXXXII.*

BY OLIVER HEAVISIDE.

(*Continued from page 352.*)

The characteristic of the whole combination, whose vanishing settles the admissible rates of subsidence, may be taken to be the conductance operator at any point, specialised by regarding p as a constant, all other forms being derivable from it. The normal functions are always entirely real when electric energy alone is concerned, and also when magnetic energy alone is concerned, though the latter does not occur in the above diffusive applications. In intermediate cases, the p's may be either real or complex. There is more to be said about these things in other electrical applications, but the present remarks are sufficient for the immediate purpose.

There is no material alteration when, by means of cross connections, we convert the above arrangement of cables entirely in sequence into a network of cables, of any degree of complication. To make the normal system complete, it must be continued over all the branches. We may use different symbols to indicate position, or we may use the same symbol with a different range. These things are immaterial. We still have to regard the normal system, though made up of many parts, as a single system, self-contained. At the same time, as before, any parts thereof may be left out, provided the proper operators are employed to sum up their reaction upon the retained parts.

§ 327. We should now point out how a normal solution, as above specified, differs from what I have usually called the operational solution. There are likenesses and differences. Let the electrical arrangement be the same, either a single circuit of cables or a network; but now consider how to find the operational solution expressing the effect all over the combination due to impressed force at any point therein. It may be impressed voltage e, or impressed gaussage h. The former will create a discontinuity in the potential, the latter in the current, and these constitute the effective sources of disturbance, whereby energy is brought into the combination. We have here a difference from the self-sufficiency of a normal system.

We have to find V (and C) all over due to e or h; say $V = Xe$, for example. The form of X is wanted. Since e is at a definite point, whilst V is anywhere, X is a function of x, specifying position in the combination. It is not the same function (in its expression) in different branches, but since all the different forms have to be harmonised, we may still regard X as a whole, changing its form of expression as we pass over the combination. In this respect it is like the normal function. But at the same time, it is a function of p, the time differentiator, and varies in form as concerns p as well as x, because p enters along with the electrical constants.

To find X fully, we proceed as in the case of a normal function, to divide the combination into sections involving only one characteristic. But we do not assume that p is constant in the characteristic. It remains what it is fundamentally, a differentiator. So, in the general solution of any section, say $V = av + bw$, the a and b are not now constants, but time functions, and v, w are not merely algebraical functions, but differential operators. We may write $V = va + wb$, if we wish to explicitly indicate that a and b are operated upon by u and w. But this is a matter of convention. A cart may be pulled or pushed. Another form is $V = (v + jw)\,a$. Here there is but one time function explicitly. The other is ja, where j is an operator.

Now supposing we have found the general solutions of V for every one of the sections, we have next to harmonise them by the conditions at the junctions. This process is, up to a certain point, formally like that of harmonising the different parts of a normal function. The difference comes in when, say finally (though it may be done initially) we treat the section containing the impressed force. There is nothing special there in a normal solution. But in the operational case we have an additional split. The section is made two sections, and there are two auxiliary conditions, as, continuity in C, and a jump in V produced by e. The result is that all the time functions in all the branches become known in terms of e. Or, in another form, in $V = Xe$, we know the operator X completely throughout the combination, and there is nothing left over to be fixed by extra data. In the case of the normal system, on the other hand, its size is left quite indefinite. Apart from this, the normal system constitutes a succession of values making it be a numerical function of x. It is one of a set, for the constant p in it may have any one of a particular series of values. It is different in an operational solution. The operand e is any function of the time, and X by itself is not numerical. But the determinantal equation is implicitly involved. For if we put $e = 0$, producing $0 = X^{-1}V$, the latter is the general characteristic of the solutions when free from impressed force. If it is, as in most of our applications, a rational equation, then $X^{-1} = 0$ finds special solutions, of the type $\epsilon^{pt} \times f(x)$. This brings us to the normal functions again. I have shown how to expand $V = e/X^{-1}$ in normal functions when they are appropriate. From the examples given, it will be seen that the operator X itself may be regarded as expressing the type of the normal function (apart from size), viz., by making p in it become constant and assume one of the critical values. It then also simplifies in form, in virtue of the determinantal equation. The greater generality of the form of X is essential. The normal system cannot be more than it is. The other has to cover all possible cases, and is constructed to do it.

Similar remarks apply when the source is h, impressed gaussage, equivalent to an external source of current. This brings us to the normal functions again from another point of view, viz., when there are no impressed forces given whose effect is required, but the data consist in the specification of an initial state of V and C, from which the subsequent states arise. We convert this general problem to a special case of the former by the use of impulses. There are two sorts. Let $e = p\mathrm{P}$ and $h = p\mathrm{Q}$, where P and Q are constants, or, more strictly, constant functions of the time when t is positive, and zero when t is negative. Then e is merely the impressed voltage in an impulse at the moment $t = 0$, the total of the impulse being P. Similarly, h is the impressed gaussage in an impulse of total Q. That is, as before explained, the charge Q is instantly introduced, and then left to itself. Similarly as regards P. It represents magnetic momentum. The analogue of $\mathrm{Q} = \mathrm{SV}$, where S is the concrete permittance connecting the charge Q and the voltage V, is $\mathrm{P} = \mathrm{LC}$, where L is the concrete inductance connecting the momentum P and the current C. But in the case of a cable, if S and L belong to unit length, Q and P are the length integrals of SV and LC. Now the initial state is fully specified by V and C. That is, P and Q are given, or which is the same thing, e and h. In our diffusion problems, we do not require to know C at all, that is, e equivalently, because the assumption $\mathrm{L} = 0$ destroys the momentum. That is why only $h = p\mathrm{Q}$ has been employed in discussing initial states, and the expansions required to represent them. But, in general, when L is included, we must use both e and h to obtain the proper expansions. The addition of the impulsive e is important because it enables us to treat the electromagnetic problems with generality as regards initial states, and from the operational standpoint.

§ 328. The object of the mathematical investigation of physical matters being to ascertain what happens under given circumstances, and map out the field of knowledge, so to speak, the method of normal functions, or modes of vibration, or of subsidence, or of time variation in more mixed manners, is one of the most important ways of working to the desired end. But whether it should be used, and if so, how it should be used, depends upon circumstances. There are other methods. It may be that only very partial knowledge is wanted—*e.g.*, the general nature of normal modes—and then it may be quite unnecessary to resort to operational methods, though their use will often settle matters which are obscure without them. On the other hand, operational ways are much the best in dealing with the effects of localised impressed

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

forces, and the study of such cases is often most instructive. The most serious drawback to the method of analysis into normal systems is that, beyond a certain point, the numerical examination of general results becomes impossible in any reasonable time. This is of no consequence in theory, but is a great practical objection. We should go to the operational solutions for information. We may turn them to normal systems if we want to, and if we do not, we can apply other methods to them. The most important is usually the simply periodic, from the wide application possible, involving the reduction of $V=Xe$ to $V=(X_0+X_1 i)e$, where e is simply periodic and i is the differentiator $d/d(nt)$. Some other special ways of working have been given, and I will give more later on. The discovery of practical methods of manipulating operators is a matter of importance to the future of physical analysis. Objections founded upon want of rigour seem to be narrow-minded, and are not important, unless passive indifference should be replaced by active obstructiveness. In making them rigorists make confession of ignorance. It would be more useful for them to try to extend the matter, and remove the want of rigour, if they want to. But this is merely parenthetical.

Returning to the simply periodic solution just mentioned, it may be worth while to point out two ways of connecting it with solutions in series of normal functions. Suppose we have a telegraph line of any sort, and desire to express the current C at the distant end (or anywhere else) in terms of e at its beginning. We may do this operationally, of course. Say we come to $C=Ye$. Now, given that e is impulsive, we can convert the result to a series of normal functions. Next, observing that if e is given variable in any way with the time, it may be regarded as made up of a succession of infinitesimal impulses, we see that the last solution in normal functions, by being used as the element of a time integral, enables us to express C when e is variable. Lastly, by choosing e to be simply periodic, the result must be equivalent to that which may be obtained directly from $C=Ye$, by the transformation $p=ni$. The method described is a very complicated way of getting the simply periodic solution, but its execution and verification is quite feasible in some cases.

The process is reversible, if we are in possession of all the steps. But if not, if we only know the simply periodic solution, obtained directly from the operational, there is another and much shorter way of passing to the solution when e varies anyhow—namely, by analysing an impulse into simply periodic variations. Thus, the impulsive voltage $e=p\mathrm{E}$ is equivalent to

$$p\mathrm{E}=\frac{\mathrm{E}}{\pi}\int_0^\infty \cos nt\,dn, \tag{113}$$

by (54) § 271. The simply periodic solution for the element $(\mathrm{E}/\pi)\cos nt\,dn$ is obtained by operating on it by Y. So

$$\mathrm{C}=\frac{\mathrm{E}}{\pi}\int_0^\infty \mathrm{Y}\cos nt\,dn=\frac{\mathrm{E}}{\pi}\int_0^\infty\left(\mathrm{Y}_0+\mathrm{Y}_1\frac{d}{d\,nt}\right)\cos nt\,dn \tag{114}$$

expresses C due to an impulsive voltage, and therefore, by a time integration, as before, we express C due to any varying e by the second method. This process can also be practically carried out, in some cases, by the evaluation of the integral. But I am afraid that, in general, the evaluation of the definite integral will present much difficulty. Considering the extreme complication introduced into normal systems by the inclusion of gradual propagation into the wires as well as along them, the process (114) seems at first sight rather enticing. It looks so simple. So it is, in idea; but if we cannot effect the integration, the integral does not tell us any more than the operational solution itself. So I found it some years ago, when I desired to trace the progress of an elastic wave along a resisting wire. The integral was unmanageable. But the operational solution itself was amenable to treatment by a specially-invented process, which had its foundation in the physical ideas involved, and which proved to be relatively simple in execution. In connection with this matter, the converse process should be noticed, viz., the transformation of definite integrals to operational form, with a view to their evaluation by any means that may then present itself. This is often a very useful practice.

But the transformation from $C=Yp\mathrm{E}$ to (114) requires to be done with caution. It may be the case that the physics is such as to show that the process is legitimate. But the legitimacy cannot be asserted when Y is an arbitrary operator, of unknown meaning. The resulting integral may not be equivalent, or may be equivalent only within a certain range. That there should be failures in this application of (113) will be understood, at least partly, by considering the application or misapplication of Fourier's theorem in the definite integral form (55), § 271, to a function which does not vanish at infinity, particularly if it is infinite itself there.

§ 329. There is little more to be said about the submarine cable without self-induction, which has been principally useful as a convenient basis upon which to rest the theory of diffusion. The application, however, of the zeroth Bessel function may be continued in a generalised form, since the Bessel functions are of great importance in mathematical physics, and have many applications in electromagnetism.

Take the problem of § 324, but now put a terminal arrangement Z_1 at $x=\lambda$, instead of having a short-circuit there. The resistance operator at the point λ is now

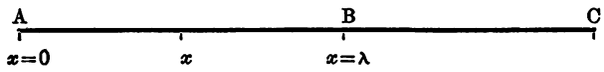
$$Z=Z_1+\frac{R_0}{q_0\lambda}\frac{I_0(q_0\lambda)}{I_1(q_0\lambda)}, \tag{115}$$

by (101), using the same notation, and it follows that if the initial state is Q at the point y, the resulting potential is

$$V=\sum\frac{QI_0(q_0x)\,I_0(q_0y)e^{pt}}{-\left(\frac{q_0}{R}I_1(q_0\lambda)\right)^2\frac{dZ}{dp}} \tag{116}$$

by the formula (83), § 322, applied to the present case, Z being given by (115), and $Z=0$ being the determinantal equation.

Now choose Z_1 to be another Bessel cable exactly like the first, but turned the other way, so that the zero conductance is at the far end. Then we make a single cable A B C, whose



conductance and permittance are greatest at B, and fall off linearly to zero at A and C. The solution (16) relates to the left one, the right one being uncharged. The resistance operator at B is twice that of either cable, or

$$Z=\frac{2R_0}{q_0\lambda}\frac{I_0(q_0\lambda)}{I_1(q_0\lambda)}. \tag{117}$$

This is such that e/Z is the current produced by e at the point B.

But it is clear on consideration that if this Z be used in (116), that result is erroneous, if limited to the roots of $I_0(q_0\lambda)=0$. For every normal system then has a node at B. This is perfectly right as regards the normal systems concerned when e is at B, because it charges the two cables symmetrically but oppositely, so that $V=0$ at B when e is removed. But it cannot be right in general, for the cables may be charged symmetrically so as to produce no current at B. Besides $I_0(q_0\lambda)=0$, we require another condition giving nodes to the current at B in a set of normal systems.

In fact, if in (115) we let Z_1 be nearly, but not quite, the same as the other term, say by the length of the right cable being slightly different from that of the left one, it will be found that the roots of Z divide into two sets, approximately those of the sum of the operators and of their difference. In the limit, the first lot lead to $I_0(q_0\lambda)=0$, with potential nodes at B, and the second lot to $I_1(q_0\lambda)=0$, with current nodes at B, the I_1 function being the derivative of I_0. The first set of normal systems are solely concerned when the initial state is such as to produce no potential at B, and the second set when such as to produce no current there.

Digitized by Google

I have introduced this example to illustrate the need of caution in the treatment of normal systems in peculiar cases. It is a necessity for the validity of the expansion of an arbitrary initial state in normal systems that every possible normal system should be included. But it usually happens in these peculiar cases that the peculiar results can be foreseen. It may be noticed that in the denominator in (116), representing $-c^2Z'$, the quantity c vanishes at the point B for all the missing normal functions. The reader has already been cautioned not to choose a point where v vanishes in the alternative form v^2Y'. If we chose Z at some other point, between B and A or C, there would be no failure.

In the treatment of this problem by the operational solution, there is no room for hesitation. Put Q at y in the left cable, and find the resulting V in the usual way. We require, of course, to use the second solution, $K_0(qx)$, along with $I_0(qx)$. The result is, writing q instead of q_0, for convenience, and R instead of R_0,

$$V_2 = I_0(qy)\left\{\frac{\pi}{2}K_0(qx) - \frac{I_0(qx)}{2q\lambda I_0(q\lambda)I_1(q\lambda)}\right\}RpQ, \qquad (118)$$

at x, on the right side of y; and the same expression with x, y interchanged serves when x is on the left side. This result is explicit in making

$$I_0(q\lambda)I_1(q\lambda) = 0 \qquad (119)$$

be the determinantal equation when (118) is expanded in a series of the normal functions $I_0(qx)$, and shows the two sets. The $K_0(qx)$ function, though required in general, then disappears altogether. Developing (118) by the expansion theorem, we get

$$V_2 = V_0 - \Sigma\frac{RpQI_0(qx)\epsilon^{pt}}{\{q\lambda I_1(q\lambda)\}^2} - \Sigma\frac{RpQI_0(qx)\epsilon^{pt}}{(q\lambda)^2 I_0(q\lambda)I_1'(q\lambda)}, \qquad (120)$$

where the first summation is subject to $I_0(q\lambda) = 0$, and the second to $I_1(q\lambda) = 0$. The accent means differentiation to $q\lambda$. There is a steady term V_0 because there is no earth connection. It is obtained as usual by making $p = 0$ in the operational solution (118). The result is

$$V_0 = \frac{Q}{S\lambda^2} = \frac{Q}{\text{total permittance}}, \qquad (121)$$

if the permittance per unit length is Sx in the first cable, and symmetrically in the second. The change to the oscillating functions $J_0(sx)$ and $J_1(sx)$ by means of $q^2 = -s^2$ is obvious. But this is a special case of the next investigation, so it is only needful to record the results as above.

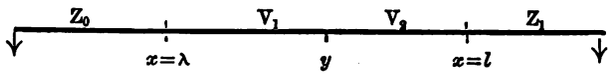
§ 330. Passing now to the general case involving the zeroth Bessel functions of both kinds we can obtain our results very shortly and symmetrically by the operational method. Let terminal arrangements Z_0 and Z_1 be put on at the points $x = \lambda$ and l, in a cable subject to the circuital laws

$$-\frac{dV}{dx} = \frac{Z}{x}C, \qquad -\frac{dC}{dx} = Yx V, \qquad (1)$$

V and C being the voltage (transverse) and current at x, where the resistance and leakance operators per unit length are Z/x and Yx. Here Z and Y are independent of x, and are preferentially of the forms

$$Y = K + Sp, \qquad Z = R + Lp, \qquad (2)$$

R, L, K, and S being constants, being the values at the point $x = 1$ of the resistance, inductance, leakance and permittance per unit length. It is merely the introduction of variation



with x in the manner specified that introduces Bessel functions.

The characteristic of V, obtained by eliminating C from (1), is

$$\frac{1}{x}\frac{d}{dx}x\frac{dV}{dx} = YZV = q^2V. \qquad (3)$$

Later on, we can give different meanings to q, according to those assumed for Y and Z.

The two solutions of the characteristic are

$$I_0(qx) = 1 + \frac{(qx)^2}{2^2} + \frac{(qx)^4}{2^2 4^2} + \frac{(qx)^6}{2^2 4^2 6^2} + \ldots$$

$$K_0(qx) = \frac{2}{\pi}\left\{-I_0(qx)\left(\log\frac{qx}{2} + \gamma\right) + \frac{q^2x^2}{2^2} + (1+\tfrac{1}{2})\frac{q^4x^6}{2^2 4^2} + (1+\tfrac{1}{2}+\tfrac{1}{3})\frac{q^6x^6}{2^2 4^2 6^2} + \ldots\right\}, \qquad (4)$$

where $\gamma = 0{\cdot}5772$ is a certain constant introduced to make $K_0(qx)$ vanish at infinity. That these are solutions of the characteristic is easily verified; and since they are not in constant ratio, it follows that they are sufficient to express all solutions directly or indirectly. That is,

$$V = \{I_0(qx) - jK_0(qx)\}A, \qquad (5)$$

where A and jA are any time functions, is the general solution of the characteristic, j being any operator.

When qx is numerical and positively real the I_0 function is like ϵ^{qx}, finite at the origin and increasing continuously to infinity at infinity. The K_0 function, on the other hand, is like ϵ^{-qx}, in falling continuously to zero at infinity. It is, however, not finite, but infinite at the origin. Both I_0 and K_0 are always positive when qx is positive.

Now construct the operational solutions for e and h at the point y. The characteristic fails at that point, so we have two forms, say

$$V_1 = \{I_0(qx) - \alpha K_0(qx)\}A, \qquad (6)$$

$$V_2 = \{I_0(qx) - \beta K_0(qx)\}B, \qquad (7)$$

where V_1 holds when x is on the left, and V_2 when on the right side of y.

In the case of e, we have

$$e = V_2 - V_1, \qquad C_1 = C_2, \qquad (8)$$

at the point y. These conditions, applied to (6), (7) determine A and B, and produce

$$V_1 = \frac{\pi qy}{2}e\frac{(I_{0x} - \alpha K_{0x})(I_{1y} - \beta K_{1y})}{\alpha - \beta}, \qquad (9)$$

$$V_2 = \frac{\pi qy}{2}e\frac{(I_{0x} - \beta K_{0x})(I_{1y} - \alpha K_{1y})}{\alpha - \beta}, \qquad (10)$$

which are quite general, as due to the source e. The operators α and β enable us to introduce terminal conditions. Say

$$V = Z_1C \text{ at } x = l, \quad V = -Z_0C \text{ at } x = 0, \qquad (11)$$

These determine α and β, thus,

$$\alpha = \frac{I_{0\lambda} - (q\lambda Z_0/Z)K_{0\lambda}}{K_{0\lambda} - (q\lambda Z_0/Z)K_{1\lambda}}, \qquad \beta = \frac{I_{0l} + (qlZ_1/Z)I_{1}e}{K_{0l} + (qlZ_1/Z)K_1 l}. \qquad (12)$$

Equations (9), (10) are now made fully explicit in terms of the terminal operators, and may be developed in Bessel series.

As regards the notation, I_1 and K_1 are the derivatives of I_0 and K_0; and, to ease matters, $I_0(qx)$ is denoted by I_{0x}, and similarly for the rest.

When h is the source, we still use (6), (7), but instead of (8) we have the conditions

$$V_1 = V_2, \qquad C_2 - C_1 = h, \qquad (13)$$

at y. These find A and B, and make

$$V_1 = \tfrac{1}{2}\pi Zh\frac{(I_{0x} - \alpha K_{0x})(I_{0y} - \beta K_{0y})}{\alpha - \beta}, \qquad (14)$$

$$V_2 = \tfrac{1}{2}\pi Zh\frac{(I_{0x} - \beta K_{0x})(I_{0y} - \alpha K_{0y})}{\alpha - \beta}. \qquad (15)$$

The expressions for α and β are the same as before. The determinantal equation of normal systems is

$$\alpha = \beta. \qquad (16)$$

The h solutions are required to represent initial states of potential, and the e solutions those of current. In obtaining them use was made of the identity

$$I_0(z)K_1(z) - I_1(z)K_0(z) = -\frac{2}{\pi z}, \qquad (17)$$

which often turns up in these investigations.

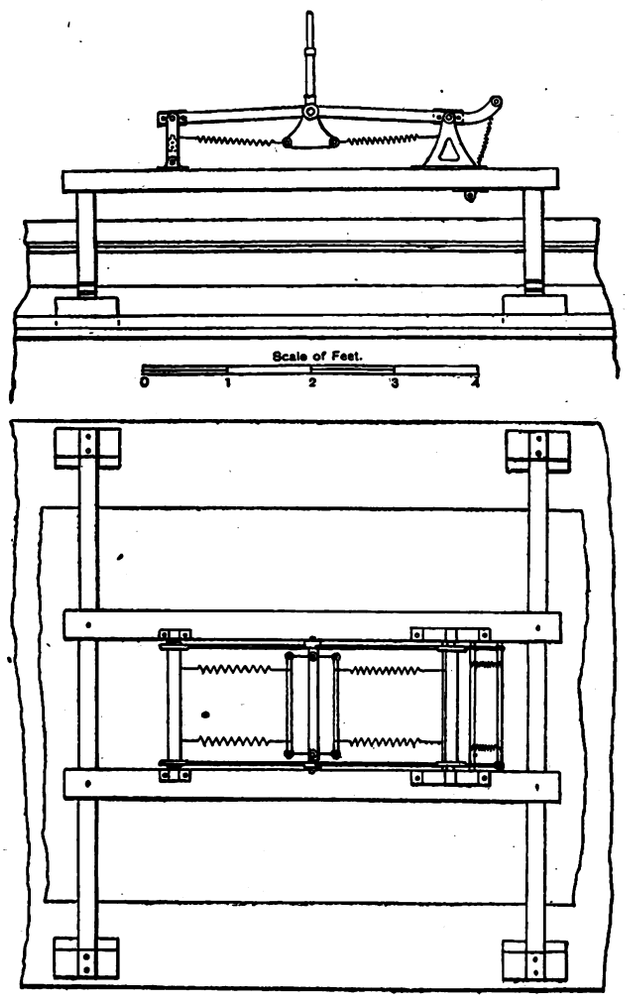
THE SIEMENS AND HALSKE SLIDING CONTACT SYSTEM FOR ELECTRIC TRAMWAYS.

The accompanying illustrations show in some detail the well-known sliding contact collector of Messrs. Siemens and Halske. This apparatus, which is intended to perform the same function as its American congener, the trolley, in overhead wire electric traction, consists of a metal frame, pivoted and spring-supported on the deck of the car; the upper part of the frame carries a horizontal contact bar extending for a transversal length of 4ft. or 5ft., and made of special metal. This bar slides with constant pressure on the line wire.

As compared with the ordinary trolley, or rolling contact collector, the Siemens apparatus offers the great advantage of ensuring permanent communication with the supply line under all conditions. It entirely does away with the frequent



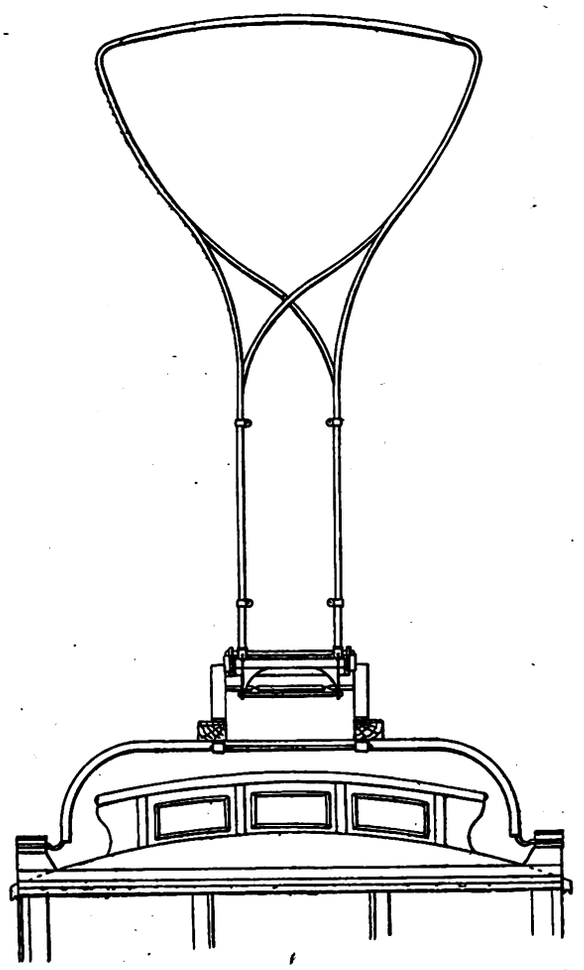
Siemens and Halske Sliding Contact System. Longitudinal Elevation and Plan of Mounting.

interruptions of contact due to the jumping of the trolley, especially on curves or passing under frogs, wire hangers, &c., when the speed is not kept within a low limit.

Objection has been raised against the use of the sliding contact on account of the considerable friction and the consequent noise and wear of the working parts. Messrs. Siemens and Halske claim, however, that the noise with the sliding collector is not greater than that experienced with the trolley, and, as regards the wear, by constituting the contact bar of a special soft alloy the line wire is not only protected from any deterioration, but its lower surface becomes gradually covered with a layer of particles from the softer metal, the contact thus becoming improved. All the wear is taken by the contact bar, which is interchangeable, and may be easily replaced. In order not to concentrate the wear on a single point of the bar, the line wire is stretched with slight deviations from the axis of the track, making a kind of zigzag.

A recent improvement introduced by Messrs. Siemens into this system consists in the substitution of a soft alloy contact bar with an aluminium channel, of U-shape and filled with grease, so as to ensure a certain lubrication of the contact. It is stated that by this contrivance all noise is practically avoided, and less power is lost in friction, beside which the renewal of the slider bar need not be so frequent.

If the latter claims should be confirmed after long practical experience, the Siemens apparatus may be expected to replace the trolley in most applications of electricity to traction, and



Siemens and Halske Sliding Contact System. Transverse Elevation.

especially where the speeds are greater than usual. The Siemens and Halske collector has been working successfully at Hanover, Dresden, Bucharest, Lemberg, Bochum, Barmen, Basle, Vienna, Berlin, Pankow, &c.

THE "HORNSBY" WATER-TUBE BOILER.

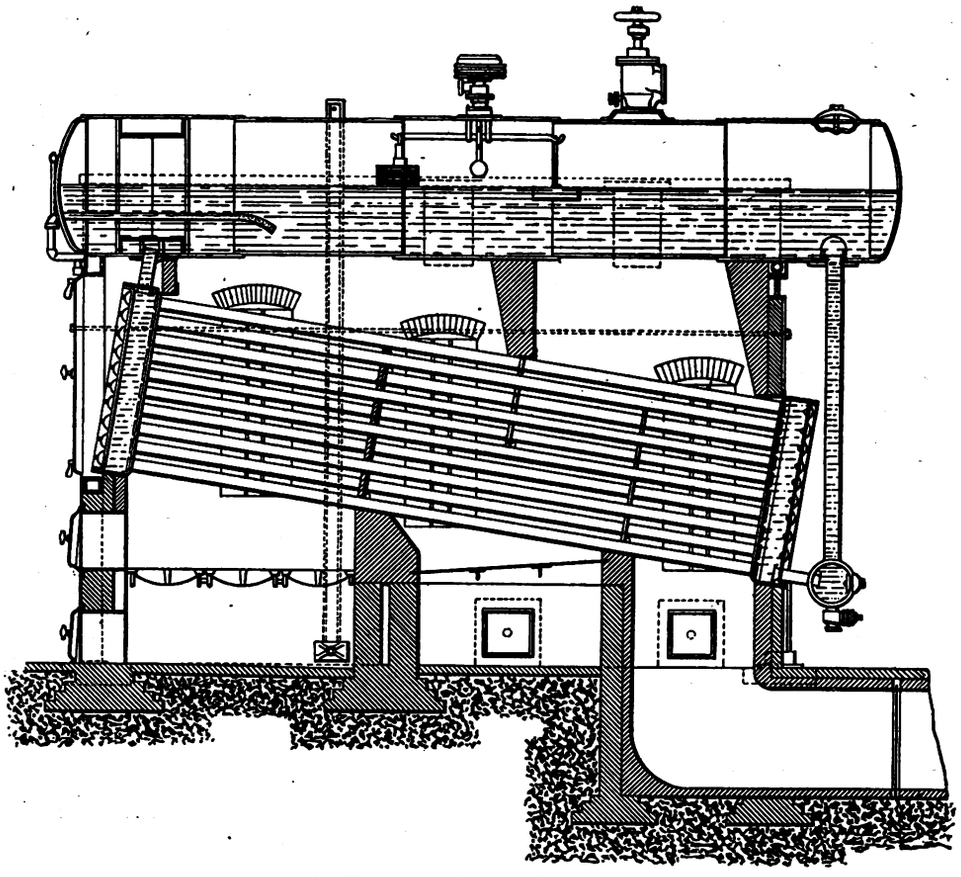
Messrs. Hornsby and Sons, of Grantham, have for some time past been conducting trials and making experiments with a view to perfecting a type of steam generator which is most commonly used in electric supply stations—namely, the water-tube boiler. The result of their inventions has attained the form shown in the accompanying vertical section of the boiler, and two boilers of this type and pattern have been erected at the Woking electric supply station, where, we understand, they have given satisfaction.

It will be seen that the "Hornsby" boiler possesses several features which will distinguish it from the class of water-tube boiler commonly met with. One of the most striking features is the arrangement for giving efficient circulation through the lower tubes, the vertical return tube delivering the water to the header opposite to the lowermost layer of tubes. This must tend to increase the evaporative efficiency and steaming capacity of the boiler, while obviating the risk of breakdown

Digitized by Google

due to the choking of the lower tubes with steam. Another valuable feature is the provision of a water separator at the top of the up-take tube, this separator consisting of an annular chamber inside the steam drum. By its action the steam passes into the steam space in a much drier condition than if compelled to bubble up through the water.

has a separate header, is said to be beneficial in preventing the entry of cold air between the tube ends. It should be stated that the front ends of the tubes are expanded to facilitate the drawing out and replacement of tubes. The illustration shows that the rear tube ends and header are carried beyond the brick setting, thereby enabling any defect in the tubes at this



Hornsby Water-tube Boiler. Longitudinal Section.

The tube headers both at the front and back ends of the tube stack are each made in one piece, an arrangement which is found to be conducive both to strength and to economical steaming. The absence of gaps between the headers at each end, such as will occur where each vertical column of tubes

part to be readily detected, and any repair to be easily carried out. The boiler can be adapted for burning either dry or bituminous coals, and, as we have already stated, is said to give very satisfactory results. Results of actual trials are not yet, however, forthcoming.

GERMAN WIRING RULES.*

The Special Committee of the Verband Deutscher Elektrotechniker, which was appointed during the Annual Meeting at Munich last year, has now (January, 1896) revised and approved of the proposed wiring rules (*see* also *The Electrician* of May 24, 1895, page 116, and of August 2, 1895, page 443). The Verband has now published the full text of the rules, and hopes that electrical engineers and manufacturers in Germany will speedily adopt the rules, though the Verband has, of course, no legal right to enforce them.

Much discussion arose as to whether the sizes of fuses should be determined by the current intended to traverse them or by the section of the conductor to be protected. A second much-discussed question was the amount of insulation required. It was argued that whilst from a purely theoretical point of view it was correct to proportion fuses to the current, but difficulties were experienced in the practical application of this principle. In many cases to keep the fall of potential within certain limits the section of the conductor has to be taken considerably larger than required by the current, which would necessitate specially-constructed terminals between the conductors and fuses. Standards for fuse blocks and fuses having been already adopted at Munich, it was further argued that these standards must be adhered to, as they had been already accepted by the German electrical industry. If the size of the fuse were to be determined by the current, changes would be required every time that lamps were added. In consideration of these circumstances the Committee adopted the principle that the sizes of fuses were to be determined by the section of the wire intended to be protected.

With regard to the right amount of insulation for installations, two formulæ have, so far, been in use. One was $R=K\frac{E}{I}$, where E represents the potential, I the maximum current, and K is a coefficient. No mention is made of the number of lamps, and, as every electrician knows, the difficulty to obtain a good insulation lies not in the long run of wires, but in the joints, fuses and switches, so that a disregard of the number of lamps cannot be technically justified. In the so-called Vienna formula the coefficient K is equal to 5,000. Accordingly, a 100-volt installation for 2,000 50-watt lamps would require an insulation resistance of 500 ohms. The same resistance would suffice for a 100-kilowatt motor plant, together with its supply conductors. It is, of course, at once clear that in this latter case a higher resistance not only can, but must be obtained, if both installations are to offer the same degree of safety against fire. One can see that the formula in question does not suit both cases, and to rectify this state different insurance companies have adopted formulæ in which the number of lamps is brought into consideration. In general $R=Kn$ is the formula, in which n represents the number of lamps, and K is a coefficient which depends upon the potential, the kind of current, and the more or less severe conditions required by the insurance companies.

In the Phœnix formula, the coefficient for potentials up to 220 volts continuous current is $12{\cdot}5\times10^6$, and in alternating current 25×10^6. According to this, a continuous-current installation of 2,000 lamps would require 6,250 ohms, and the same installation with alternating current 12,500 ohms insulation resistance. This is

* Abstract from the *Elektrotechnischc Zeitschrift.*

Digitized by Google

12½ and 25 times larger than is required by the Vienna formula. Such a high insulation can of course be easily obtained under favourable conditions, but it cannot be relied upon in all cases, and for this reason the Phœnix formula must be considered as too severe for general practice. Even the Phœnix office itself has declared it so, as in addition to the paragraph on insulation resistance, it is stated the representative of the Company is empowered to allow smaller insulation resistance in certain cases. Under these circumstances it will be scarcely otherwise than that the exception will become the rule, and for this reason the Committee of the Verband has reduced the coefficient from 12,500,000 to 1,000,000. An insulation resistance of $\frac{1,000,000}{n}$ for the whole installation would, however, offer no guarantee of fire safety. In fairly good work 10 megohms per lamp can easily be reached. Suppose that, in an installation of 2,000 lamps, all lamps are fitted well except 10. The insulation of the 1,990 lamps at 10 megohms each is about 5,000 ohms, while the insulation of the 10 badly-fitted lamps may be together only 1,000 ohms. The reduction of the resistance to 1,000 ohms is likely to be dangerous, but in spite of this a test of the whole installation would show an insulation resistance of 830 ohms, which is considerably more than the 500 ohms required by the Verband's rule. The instance just mentioned shows that even if the number of lamps is regarded, the formula does not always offer a guarantee for safety. To minimise this evil the Committee of the Verband has made it a rule that not only must the whole installation comply with the formula $R = \frac{10^6}{n}$, but no part of the installation must have a smaller insulation resistance than $10,000 + \frac{10^6}{n}$. The introduction of the constant factor of 10,000 ohms is for the purpose of avoiding the danger indicated above, which could arise in an otherwise good installation through a few badly-installed lamps. In tests the wiring may be subdivided to suit convenience, and the smaller the divisions the easier it will be to comply with the formula, as the influence of the constant factor of 10,000 ohms becomes smaller, the smaller the number of lamps.

The following is an abstract of the more important rules. These rules apply to electrical installations with potentials up to 250 volts between any two conductors or one conductor and earth, with the exception of underground networks and electro-chemical plants :—

Copper conductors must possess such a conductivity that 55 metres of wire of 1 sq.mm. section have at 15°C. a resistance of not more than 1 ohm. The maximum permissible current for copper wires and cables is as given in the following table :—

Nearest S.W.G.	Section in sq. mm.	Current in amperes.	Nearest S.W.G.	Section in sq. mm.	Current in amperes.
19	0·75	3	19/17	35	80
18	1·0	4	19/15	50	100
17	1·5	6	19/13	70	130
15	2·5	10	19/12	95	160
13	4·	15	37/14	120	200
12	6·	20	37/13	150	230
9	10·	30	37/12	210	300
7/16	16·	40	61/13	300	400
19/18	25·	60	91/12	500	600

The smallest permissible cross-section for conductors is 1 sq. mm. (about No. 18 S.W.G.), for fittings ¾ sq.mm. (about No. 19 S.W.G.), and for flexible conductors 1 sq. mm. These latter must not be fixed permanently along ceilings or walls. For fixing conductors, porcelain insulators, cleats and tubes can be used ; *wood casings are not permitted*. The size of fuses is conditioned by the section of the smallest of the conductors to be protected, and the highest permissible fusing current is to be taken from the following table :—

Nearest S.W.G.	Section of conductor wire in sq. mm.	Working current for conductor in amperes.	Fusing current in amperes.
19	0·75	3	6
18	1	4	8
17	1·5	6	12
15	2·5	10	20
13	4	15	30
12	6	20	40
9	10	30	60
7/16	16	40	80
19/18	25	60	120
19/17	35	80	160
19/15	50	100	200
19/13	70	130	260
19/12	95	160	320
37/14	120	200	400
37/13	150	230	460
37/12	210	300	600
61/13	300	400	800
91/12	500	600	1,200

In installations on the three-wire system the fuses of the middle wire must be 1½ times the size of the fuses of the outer wires. When the middle wire, however, is permanently earthed, no fuse is required. The insulation resistance of the whole conductor network to earth must be at least $\frac{1,000,000}{n}$ ohms, and, in addition, each main branch must have an insulation of at least $10,000 + \frac{1,000,000}{n}$ ohms. In these formulæ n is the total number of 50-watt glow lamps connected ; one arc lamp, motors, or other energy-consuming apparatus being reckoned as equal to 10 glow lamps.

In making insulation tests to earth with continuous current the negative pole of the generator should, if possible, be connected to the conductor which is to be tested. The readings must only be taken after one minute's electrification. All insulation tests must be made with the working pressure. In multi-wire systems the pressure at the lamps is to be taken as the working pressure. In all the insulation tests all glow lamps, arc lamps, motors and other apparatus must be disconnected, but all fittings, fuses and switches must be in the circuit.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, January 24th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read : (1) "Exhibition of Some Geometrical Instruments," by E. Scott and Signor Monticolo ; (2) "On Resultant Tones," by J. D. Everett ; (3) "Experiments with Incandescent Lamps," by Sir David Salomons.

SATURDAY, January 25th.

THE INSTITUTION OF JUNIOR ENGINEERS.

7 p.m. Anniversary Dinner at the Westminster Palace Hotel Victoria-street.

MONDAY, January 27th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture II. : "Alternate-Current Transformers," by Dr. J. A. Fleming, F.R.S.

TUESDAY, January 28th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read : "Recent Developments in Gas Engines," by Dugald Clerk.

WEDNESDAY, January 29th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read : "Standards of Light," by W. J. Dibdin.

THURSDAY, January 30th.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Annual General Meeting at 25, Great George-street, Westminster. Papers to be read : (1) "Telemeters and Range-Finders for Naval and Other Purposes," by Profs. Barr and Stroud ; (2) "Calculation of Horse-Power for Marine Propulsion," by Lieut. Col. Thomas English.

FRIDAY, January 31st.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Annual General Meeting at 25, Great George-street, Westminster. Paper to be read : "Notes on Steam Super-heating," by William H. Patchell.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at the St. James's Hall Restaurant (Banquet Room), Regent-street, W.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Geneva Exhibition.—The Swiss National Exhibition begins at Geneva on May 1st and terminates October 15th. Colonel Turrettini, Mayor of Geneva, the distinguished electrical engineer, is president of the exhibition, and it is expected that the electrical exhibit will be a fine one. There will be a travelling footpath, operated by electricity, traversing the great machinery hall ; horseless cabs driven by electricity, &c, and Prof. Pictet will display his inventions for producing intense cold.

THE ARRANGEMENT OF OUR IDEAS.

Apparently the President of the Institution of Electrical Engineers has been for the past ten years so deeply immersed in the toils of his professional career as to be unfamiliar both with the methods of the technical colleges and with the views of Mr. OLIVER HEAVISIDE. Perhaps we ought to rejoice at the circumstance, because when we read his Presidential Address it is the more delightful to find him independently arriving at the same ideas and expounding them with all the freshness of original discovery. For apart from the perplexities of a mathematical intermezzo, and the scherzo of an ether-less theory of waves in space, the composition to which he treated his audience combined sundry familiar themes. The opening (after a military fanfare by way of prelude) was in the allegro manner, a cheerful progression of chords—not by any means all common. Then a modern *motif*. Why not abandon all the century-old stale methods of working out a theme? Nothing easier. Throw aside the old fundamental starting point. Remodel your ideas in the new manner. And the concluding coda of the performance repeating the introductory movement brought down hearty cheers.

What, then, did Dr. HOPKINSON imply in his suggestion that we should remodel our ideas as to electric actions, and treat them from the standpoint of modern discoveries? How far does he wish us to go? Clearly the exposition of a science in which all the phenomena are interlinked might begin with any one of them. One might start with the fundamental fact of thermo-electric transmission of heat, or of ARAGO's rotations, or of the electric motor, and work out thence all the other electric phenomena. The historic method, as Dr. HOPKINSON pointed out, begins with electrostatics and the attractive properties of rubbed amber. But now we are invited to a step forward, and start, not from the phenomenon of *charge*, but but from that of *current*—of current as generated by chemical

Digitized by Google

means. About this phenomenon, rather than the older phenomenon of charge we are to arrange, or rather re-arrange, our ideas; and following up this plan we are shown that many of the more complex notions, even that of the electromagnetic theory of light, can readily be brought into line and modernised.

But it is not quite clear from the address how far the PRESIDENT is willing to go in re-arranging our ideas on the fundamental basis of the electric current as a simple phenomenon. If he goes no further than this: that for a man studying the science for the purpose of making himself useful in the industrial applications of electricity, it is best to take the so-called "current" as a simple directed quantity, and to build up a knowledge of the facts about it without first having recourse to a glass rod or a piece of sealing-wax, Dr. HOPKINSON will have the support of every one conversant with the subject. For in all our technical colleges that method of approaching the subject is successfully employed; and in modern books, such as Prof. AYRTON'S "Practical Electricity," it is carried out just as Dr. HOPKINSON would wish. If it is suggested, however, as the wording of the Address would lead us to suppose, that the electric current should be taken as the fundamental notion upon which all other notions in electricity and magnetism are to be built, there will be raised many dissentient voices. It is true that we may begin with the current or the group of facts which are called the phenomena of the current, and arrange our ideas in a way which will give a consistent account of everything that we observe in electrostatics and magnetism (as indeed is illustrated by the very neat example relating to electrostatic attraction in the Address), but it by no means follows that such a course is desirable. If the whole science were built up rigidly upon this solitary basis, there would be no place in it for the inquiry as to what an electric current may be, or why we have the heating effect, the magnetic field and the electrolysis accompanying each other. We cannot take Dr. HOPKINSON to mean that we are to be content with the experimental facts.

When during the temporary absence of the ordinary attendant the stoker is left in charge of the dynamo and switchboard, there is some resemblance between the way in which he regards the machine and the way in which a scientific man regards a voltaic cell. To the man whose only experience of a dynamo has been gained by observing the running of it from day to day it is merely an entity which lights the lamps when run up to speed, and connected with which are various little tricks and requirements which a more pedantic spirit might call "the phenomena of the dynamo." For instance, if the pointer in that instrument called "voltmeter" points to 95, it can be restored to its proper place, 100, by turning this handle to the right, or if there is sparking at the brushes it can be cured by moving the rocker. These are facts which are established in his mind by indisputable experimental evidence, just as the phenomena of the voltaic cell are familiar to the man of science. Each is in his own case ignorant of the exact connection between cause and effect. It would be possible to build up a fairly useful science, beginning with the stoker's fundamental notion of a dynamo, and proceeding with such facts as might be found out by experiments on it. Improvements in dynamo design would, of course, be difficult, but it is conceivable that central stations might be built and great deal of money made by the application of a science so restricted. Our present knowledge is, of course, far more extended and far more elastic because it is built up of simpler elements; and so will our present knowledge be further extended and made pliable when we know as much about the interior actions in a voltaic cell as we know about the interior working of a dynamo.

When we seek to obtain a complete view of that which is known of electricity and magnetism, the question arises: What shall we take as our starting point? From what pole shall we proceed on our investigation? But the question is really as futile as in an electric circuit to hunt for the place where the electricity starts. The motion is essentially circuital, one may begin anywhere and trace round to the place whence we began the quest. We may discover a definite point where energy enters or energy leaves, but the cycle is necessarily re-entrant. You may begin at any point, and track the phenomena in either direction; but to your starting point you are bound to return. So is it with the mutually inter-connected phenomena of electricity, galvanism, and magnetism. Consider the general case presented by a simple electric circuit interlinked with a simple magnetic circuit. There are six important quantities, each of which depends on the others. In the electric circuit there are three things to be considered:—The (electromotive) force E, the displacement D (depending on E and on k the inductivity), and the current C (which is equivalent to the rate of change of displacement $\dot{D}$). In the magnetic circuit there are also three things to be considered—the (magnetic) force $\mathbf{H}$ (which depends on C), the displacement $\mathbf{B}$ (depending on $\mathbf{H}$ and on μ the permeability) and the rate of change of displacement $\dot{\mathbf{B}}$, on which E in the electric circuit depend. Without being very precise as to the units, and merely for the purpose of giving a general view of the dependence of these quantities, we might group them in a circle in their order, omitting C as a separate symbol, since it is the same thing as $\dot{D}$ or $\mathbf{H}$. For typographical reasons we print them here in one line:

$$E;\ Ek=D;\ \dot{D}=H;\ H\mu=B;\ \dot{B}=E.$$

The series ends with the term with which it began. Had we begun with D (the electrostatic displacement), or with $\mathbf{B}$ (the magnetic flux per unit of area), we should still have had a re-entrant series. Grouped thus in a natural cycle, there is a strict symmetry about the relations between the quantities which makes it impossible to say that any one of them is the necessary or natural starting point. They are all necessary. The true answer to the question—What shall we take as our fundamental quantity?—depends entirely upon what problem we have in hand. If we are dealing with the supply of electric current, let us by all means adopt Dr. HOPKINSON'S suggestion and take the current as our fundamental quantity and everything else as a function of the current. And if we do so in the logical way that Dr. HOPKINSON has set out we shall, along with other benefits, obtain, as he has shown, a rational system of units such as OLIVER HEAVISIDE has advocated in our columns for years past. Irrationality cannot have long to live when it is attacked by two such opponents, and from both the practical and theoretical sides at once. If, however, we are dealing with a magnetic problem, it will be convenient to take $\mathbf{H}$ or $\mathbf{B}$ as fundamentals; if we are dealing with electrostatics, E or D. HERTZ would not have made much progress with his experiments upon electromagnetic waves if he had not had a simpler mental picture of an electric displacement than is conveyed by the expression $\int C\,dt$. The important point is that all the different methods must go hand in hand and not be set in opposition to each other. For instance, if the man who looks from the electrostatic point of view can show that the energy is transmitted through the dielectric, the man

Digitized by Google

who looks only from the current point of view must not say "It is not known how the energy is transmitted" merely because his particular method does not make the matter clear. We think that herein Dr. HOPKINSON failed to do justice to the far-reaching discovery by Prof. POYNTING of the energy paths in space. Neither must he say "There is no ether" because in his limited presentation of the subject he has, by a metaphysical stretch of ideas, managed to dispense with a medium.

The true student of electricity will be prepared to take any one of the six quantities as a starting point, and deduce the others; then finding, as he must do in the nature of things, that they lead him round in a re-entrant cycle, he will look out for some entity outside the ring of phenomena which shall, on due investigation, prove a key to their real and inner nature, and to the ultimate cause of their interdependence.

DR. HOPKINSON'S PRESIDENTIAL ADDRESS TO THE INSTITUTION OF ELECTRICAL ENGINEERS.

When it was suddenly proposed to me that I should a second time be your President, I felt considerable reluctance to accept the duty. This reluctance arose from two causes. Of the first I am ashamed—pure laziness—and of it the less I say the better. The second was a *bonâ-fide* doubt as to whether I was specially suitable for the post. But it soon struck me that that was a matter for which those who proposed me were responsible, and not I who accepted, but had not sought the office. But if I felt a temporary reluctance, do not suppose that I for a moment failed to appreciate the honour which had been done me. To be called by his fellow professional men to fill the chair which has been occupied by men of such distinction as Kelvin, Siemens, Abel, Crookes, not to mention others, is an honour of which anyone may confess himself proud. After once having occupied this chair, to be called to it a second time is a greater honour, for it shows that one's efforts, however imperfect, have been generously appreciated by those for whom they were made. I thank you for the honour, and assure you I will do my best to verify, if I can, the judgment of those who proposed and you who elected me, rather than my own misgivings.

The century which is now just drawing to a close has been a time remarkable above all other times for the extraordinary development of our knowledge of the physical sciences, and in particular of experimental physics and chemistry, and for the extent of the practical application of this knowledge to useful purposes. The century has seen the discovery of the mechanical nature of heat, of the spectroscope, and of the whole of the science of organic chemistry; it has seen the enormous development of the application of the steam engine, the construction of our railway system, and the supersession of sailing vessels by steamboats. But perhaps the most remarkable illustration of this development is to be found in the science, and its application, with which this Institution has to deal. Consider what was known of the sciences of electricity and magnetism at the end of the last century. The two sciences were then quite unconnected. In magnetism the properties of permanent magnets were known—that is to say, it was known that steel needles could be rendered magnetic by rubbing with a loadstone, and that when so rendered magnetic they would tend to remain in that condition; it was known that if a magnet were broken in parts that each part would exhibit North and South poles like the magnet from which it was broken; it was also known that the earth exhibited properties of magnetism, inasmuch as a magnetic needle free to move would point, on the whole, to the North; broadly speaking, what we know to-day about permanent magnets was known, and that was about all. The practical applications were limited to the use of a magnetic needle in the mariner's compass. The knowledge of electricity was confined to what is now known as electrostatics. That certain bodies when rubbed exhibited peculiar properties, attracting and repelling each other, had long been observed; and the facts expressed by the hypothesis of positive and negative electricity were known—namely, that two pieces of amber which had been rubbed repelled each other, two pieces of glass which had been rubbed repelled each other, but a piece of rubbed glass and a piece of rubbed amber attracted each other. In a general way the proprieties of conductors, as distinguished from insulators, were also known in their relation to charges of frictional electricity. Cavendish had made elaborate investigations into the capacity of condensers, the condensers being usually of glass, and being charged by the old-fashioned frictional means. Franklin had proved the identity of the cause of lightning with the cause of the sparks produced by frictional electricity. Just one hundred years ago Galvani had made his celebrated experiments showing that the muscles of the limb of a frog were disturbed by contact with a piece of copper and a piece of zinc which touched each other; and that was the only fact which up to that time had ever been observed in the enormous group of facts which now constitute our knowledge of the production of electricity by chemical action. Shortly stated, that was the extent of our theoretical and experimental knowledge of electricity. The practical applications of this knowledge were almost *nil*. I can recall nothing excepting the provision of lightning conductors as a protection to buildings.

It is worth insisting that the additions to our knowledge of the properties of permanent magnets and of frictional electricity during the century have not been of great importance, and the practical applications of these limited branches of knowledge have been few. If one is asked what uses can be made of our knowledge of frictional electricity apart from the phenomena of currents, it is hard to name anything of importance. In like manner, in regard to our knowledge of permanent magnets, it may almost be said that the advances in practical applications have been confined to improvements in the use of the mariner's compass, which, most important although they are, have had comparatively little share in the changes in our conditions which the last hundred years have witnessed. Almost everything in the way of practical applications of electrical science has been the outcome of subsequent discoveries—the voltaic cell, discovered by Volta in the year 1800; Davy's discoveries in electrolysis, Oersted's discovery of the action of currents upon magnets, Ampère's discoveries of the mechanical action of currents upon currents, and Faraday's discoveries in electro-magnetism, not to mention the names of eminent men still living. Now, the remarkable thing is that none of these phenomena had ever been witnessed by mortal man. It was not that they were constantly occurring around us, and that the explanation had not been seen; it is the fact that the phenomena had never been experienced. It would seem that the phenomena of electric currents as Volta discovered them do not occur in nature on any substantial scale. Electro-magnets may be regarded as purely a creation of the human mind; so far as we know at present, no example of an electro-magnet is found in the natural world. The great currents produced by the action of electro-magnets have, so far as we know, no counterpart in nature—not only no counterpart in degree, but none in kind. In this respect our science differs much from many others. In mechanics and in heat we may find the phenomenon of which we make use occurring without our aid on an enormously greater scale than we are accustomed to use; changes are constantly occurring around us, and it is conceivable that we might have obtained much of our present knowledge by the aid of observation without experiments. But it is not so with electricity and magnetism. We should be puzzled even now to adequately illustrate the facts we know by observation alone without experiment.

Let us consider for a moment the practical applications which have been made of electrical knowledge during the last 60 years. The first, of course, is the telegraph. What are the scientific facts which have been used in the development of telegraphy? The currents are generated either by chemical means or electro-magnetic means. The receiving instruments either depend for their action on the action of currents upon magnets, or, in a limited number of cases, on electro-chemical

Digitized by Google

decomposition. We might put it broadly thus—that, with the exception of the distinction between conductors and non-conductors and certain properties of condensers, the telegraph could do without anything that was known up to the end of the last century, and that it wholly depends upon more recent discoveries. Much the same may be said with regard to the more recent applications; the electric light, electric transmission of power, and the rapidly-growing department of electro chemistry may all be said to be quite independent of any facts which were known before the year 1800, and entirely based upon discoveries made since. Suppose it were a fact that electricity could not be produced by friction, that we knew nothing concerning the attraction which oppositely-electrified bodies have for each other, that permanent magnets did not exist—or, in other words, that iron had no hysteresis—would it make any material difference, so far as we know, in the practical applications of electrical science to telegraphy, telephony, electric light, electric transmission of power, or electro-chemistry? The permanent magnets, which are practically used only in instruments, would be at once replaced by electro-magnets, and the apparatus would work just as it does now.

Enough has been said, I think, to show that the knowledge of electricity and magnetism which was possessed by men at the end of the last century, intensely interesting though it was, has not been the parent of the great applications of later days; that the knowledge of the last century has not grown in any great degree upon the lines which existed at its commencement, but that our advances in science, as in practice, were the result of the discoveries which were made since the beginning of the present century.

It has been a frequent practice with presidents of societies devoted to promoting some department of science, theoretic or applied, to deal with the history of the science in their presidential addresses—to show how one idea has led up to another, and how marked have been the advances made. This evening I propose to adopt a different course. What I wish to consider is, how would the theory of electricity have been arranged if the order of discovery of the facts of the science had been other than it has been? Here I owe you some words of apology. You are a practical body more immediately interested in the application of science to the service of man than in the promotion of abstract knowledge. The justification I would offer for my subject is that the science of electricity, whether viewed from the practical or theoretical side, is in a state of extraordinarily rapid advance. The rules of practice of yesterday are of little use to-day, hence more discussion is needed, more publication is needed, than in departments which are in a more stable state. Furthermore, there is no department of applied science in which the connection with theory is so close and intimate. The practical electrical engineer reads eagerly the results of those who, careless whether their work finds application or not, labour to advance knowledge; he attacks these results whether they be expressed in the ordinary speech of men or in mathematical symbols. On the other hand, much of our knowledge of electricity, viewed from the scientific side, has come from those who are concerned with practical application. Nowhere else do we find a closer interdependence of pure science and practice. In what I have to say there will be much that is trite and obvious to the merest tyro in electricity. What I wish to do is to show how the facts of electrostatics can be explained by the facts of current electricity* without hypothesis; and it is necessary to rehearse elementary principles. In a complicated subject like electricity, in which the appeals to our senses are indirect, there are open to us many ways of arranging our ideas, any one of which will give us a consistent account of that which we observe. We may take as our fundamental basis one or other of various groups of facts, and deduce others therefrom. The actual arrangement of ideas on the subject depends in a measure upon the accident of the historical order of discovery. Thus, the fact that actions at a distance between electrified bodies were known many years before the phenomena of current electricity and electro-magnetism is the reason why that part of the science which treats of such actions is to-day treated first and made the basis of the rest. The time has, I think, come when we may with advantage reconsider our position, and see whether or not our ideas may be more conveniently arranged. The arrangement which is most convenient may no doubt depend upon the phenomena which occupy the most prominent place in the practical use we wish to make of the science. Those facts are best treated as fundamental which are most frequently used, provided they are sufficiently simple. To the practical electrician, are the facts of current electricity, or of the attractions and repulsions of electrified bodies, more familiar? Surely the transference of energy by current is the agent by which almost every operation he purposes is effected, whilst the phenomena of electrostatics touch him only at points in the theory of electrometers and so forth. I propose, then, this evening to sketch out very briefly, *ab initio*, how we may base the science of electrostatics upon the theory of current electricity taken as fundamental. We might, if we pleased, drop the word "current" altogether, and substitute another. It seems hardly worth while, but I shall ask you to bear in mind that, if used to-night, it does not connote the idea of anything flowing along the conductor. It is a name for a directed magnitude, and nothing more. I shall have occasion to refer to some elementary experiments, but you will bear with me, I trust, for we are concerned with arranging the subject on as small a basis of facts as is consistent with rigid deduction. Please, then, to banish from your minds all theory on the subject, and let us imagine that the facts of current electricity are first discovered, and that it is only when these are well developed that electrostatic attractions and repulsions are found out.

In a vessel of dilute sulphuric acid is placed a piece of pure zinc, or of zinc carefully amalgamated, and also a piece of copper, platinum, silver, or carbon, the two plates not being in contact with each other. It is observed that no change takes place; the acid does not attack either plate. The two plates are now touched with the two ends of a wire of copper or other metal; immediately the zinc begins to dissolve in the sulphuric acid, and gas—which, if collected, proves to be hydrogen—is found on the copper or platinum plate. If the plates are large and near together, and the wire is not too long or thick, it becomes very sensibly heated. On separating the wire from either plate, the chemical reaction and the heating of the wire cease. When the wire touches both plates there is then development of chemical energy in the vessel of acid; but a part of this energy appears as heat, not where it is developed, but in the wire connecting the plates. Whether this energy goes across the space of air between the zinc plate and the wire, or whether it goes along the wire, we do not know; but that the two plates should be rendered continuous with each other by a wire or some equivalent is a condition precedent to the chemical reaction and to the heating of the wire.

Let two such vessels of dilute acid, with plates of zinc and copper, be provided, and let the copper in one vessel be connected metallically to the zinc in the other: nothing happens until the copper in the second vessel is connected to the zinc of the first; then both zincs are dissolved, hydrogen is liberated on both copper plates, and the connecting wires are more or less heated.

Again, varying the experiment, let the coppers in the two vessels be connected together and the zincs be connected together: no reaction or heating occurs.

The combination of a piece of zinc and a piece of copper dipping separately into a vessel of dilute acid is called a "galvanic cell" or element; a series of elements connected together copper to zinc is called a "galvanic battery." Galvanic elements and batteries take a multitude of forms; the zinc may be replaced by another metal—for example, cadmium—and the copper by platinum; many other liquids than dilute sulphuric acid may be used; but all galvanic batteries have this in common—to cause them to work, the chain or circuit must be completed by a wire touching the zinc at one end of the series and the copper at the other, and then chemical reactions occur in the cells, and heat is liberated in the metal

*I am informed by Prof. S. P. Thompson that he has for some time past in his lectures began the subject of Electricity with the consideration of currents. My attention has also been called to Prof. Ayrton's excellent book on "Practical Electricity," with the contents of which I ought to have been, but was not, acquainted, in which a similar arrangement of the subject was adopted no less than nine years ago.—J. H.

Digitized by Google

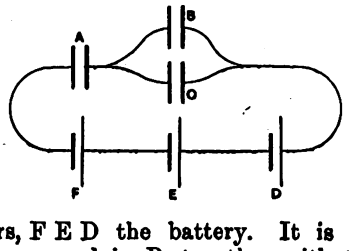
connections. The zinc and copper plates, or their equivalents, at the ends of a galvanic battery are called "poles."

Let two plates of platinum dip into dilute sulphuric acid; connect one plate by means of a wire to the zinc pole of a battery, the other plate to the copper pole. So soon as the connections are made, chemical reactions occur in the cells of the battery, the connecting wires are more or less heated, and, further, a reaction occurs in the vessel in which the platinum plates dip, the water is decomposed, gases are liberated on the two plates; if these are collected, it is found that the gas from the plate connected to the zinc pole is hydrogen, that from the plate connected to the copper is oxygen. The effects cease on detaching either wire from the platinum plate or the pole of the battery, or otherwise interrupting the continuity of the circuit. In this experiment is seen a chemical reaction liberating energy in the cells of the battery, and another chemical reaction absorbing energy in the vessel containing the platinum plates; how the energy passes from one vessel to the other we do not know.

The experiment may be varied. Let two plates of zinc or other metal dip into a solution of salt of zinc or other metal, and let the plates be connected to the poles of a galvanic battery for a time. If the plates be weighed before and after the operation, it is found that the plate which was connected to the zinc pole has gained in weight, and that the plate which has been connected to the copper has lost an equal amount. By weighing such plates, and noting the time the experiment was allowed to continue, it is practicable to examine quantitatively the phenomena of a galvanic circuit. Such pair of plates and solution of salt is called a "voltameter."

Suppose now a series of voltmeters, having in each the same metal, are connected together in a chain, a plate of one to a plate of the next, and the two ends of the chain connected to the two poles of a battery, it is found that, no matter what be the size and form of the voltameters, their position, or the arrangement of the connecting wires, there is the same gain and loss of weight of the plates in all the voltameters; it is further found that, if the zincs of the cells of the battery are weighed before and after the experiment, and if the metal used in the voltameter be zinc, the quantity of zinc dissolved is the same in all the cells, and is the same as that transferred in each voltameter. The rate of dissolution and deposit is the same in the several voltameters and cells. In a closed galvanic circuit we have, then, a measurable something the same for all cross-sections of the circuit, measurable by the quantity of zinc or other selected metal which is transferred from one plate to the other of a voltameter in a unit of time. This something has direction as well as magnitude, and as the magnitude may be represented in terms of any unit chosen by a numerical quantity C, so the direction may be represented by the sign + or −. It is arbitrarily chosen to take as + the direction from the plate which loses weight to that which gains weight through the liquid in the voltameter. The quantity C taken, with its sign, is called the galvanic or electric current round the circuit, but it must not be supposed that it is known that there is anything flowing round the circuit.

Suppose that, instead of a simple galvanic circuit, the circuit divides or branches as indicated in the sketch, in which A, B, C,



are voltameters, F E D the battery. It is found that the quantity of zinc moved in B, together with the quantity of zinc moved in C, is equal to the quantity moved in A. This gives us the idea of current in the branch B or C, and we may say that the current in A is the algebraic sum of the currents in B and C.

Not all bodies are competent to complete a galvanic circuit. Thus, if the copper wires which serve to connect the poles of the cells of the batteries and the voltameter are any of them replaced by thread, the phenomena of galvanism do not occur; if one of the wires be severed and a piece of paraffined paper interposed, the phenomena do not occur.

Thus we have a distinction of substances into those which are capable of forming continuously part of a galvanic circuit and those which are not; the former are called "conductors," the latter "non-conductors." The distinction will be found to be really one of degree.

Consider a wire forming part of the galvanic circuit: after a short time no change occurs in the wire; it is heated by the current, and it loses heat by heat conduction, convection, or radiation. It is possible by the methods of calorimetry to measure the total quantity of energy leaving the wire as heat by these agencies; it must be equal to the quantity of energy brought into the wire by galvanic agency.

Again, consider the battery itself. A certain chemical reaction is going on; zinc is being oxidised, and other reactions are occurring. Of the net amount of energy liberated per second by these, some goes to heat the battery, but some also appears in parts of the circuit external to the battery—that is, leaves the battery by galvanic agency. Thus a galvanic current is an instrument which takes energy from certain parts of the circuit and takes it into other parts of the circuit; and when the current is steady the algebraic sum of the quantity of energy taken into all parts of the circuit is *nil*. Denote by E C the quantity of energy per unit of time taken into any section, A, B, of the galvanic circuit, the positive direction of the current being from A to B. If the whole of the circuit be broken into sections, the algebraic sum of the values of E C is *nil*, but the value of C is the same for all sections; hence the algebraic sum of the values of E is *nil*. Let there be any quantity, V_a, referred to each point of the circuit, such that $V_a - V_b = E$, the condition that the sums of the values of E shall be *nil* is fulfilled. E is therefore properly described as the difference of two quantities, one peculiar to A, the other to B; it is called the difference of potential between A and B, and V_a is called the potential at A, though it is only with differences of potential that we are concerned.

Suppose now the circuit divides at A into two or more branches, joining again at B, by our definition the difference of potential between A and B is the sum of the energies taken per unit of time into the conductors A, B, divided by the sum of the currents in the conductors A, B. We have now to show that the energy taken into each of the conductors A, B, is equal to the difference of potential between A and B multiplied by the current in that conductor. This is by no means obvious, but depends on an assumption of an experimental truth, viz., that in a given conductor the energy taken into it by the current is a function of the current only, and is independent of other conditions external to the conductor. Granted this, it easily follows that, if two or more conductors be joined at A and B, the potential difference between A and B deduced from each will be the same.

As we have defined difference of potential by means of work done in a conductor when a given current exists in it, the laws of resistance must have the same basis. In the case of a homogeneous metallic conductor under given constant physical conditions of temperature, stress, and magnetic field carrying a constant galvanic current C, Joule found that the heat liberated per unit of time varies as the square of C = R C^2 when R is a constant relative to C for the conductor, Whence follows that E = R C R is called the electrical resistance of the conductor. For metallic conductors R is constant, but the constant R does not exist for all conductors; for the electric arc, for example the heat generated varies more nearly as C than as C^2, and therefore E is more nearly constant than varying as C.

We have now gained two fundamental ideas—that of galvanic current, and difference of potential. In terms of what units are we to measure them? We have only one unit to choose, because E C must be expressed in terms of our mechanical unit of power. If a unit were to be fixed at this stage, it would be natural to define either a unit of current or of resistance the ratio of $\frac{E}{C}$; for example, we might say the unit of current shall be that current whereby a unit weight of distilled water if decomposed per second; or we might say, let the resistance of

Digitized by Google

a piece of wire of defined shape and material at a definite temperature be the unit of resistance. The units in general use have an electromagnetic basis, but be it observed that all rational systems must be such that EC is expressed in some ordinary mechanical units.

(*To be concluded*)

ON A NEW FORM OF RADIATION.*

BY PROF. WILHELM KONRAD RÖNTGEN.

1. If we pass the discharge from a large Rühmkorff coil through a Hittorf or a sufficiently exhausted Lenard, Crookes, or similar apparatus, and cover the tube with a somewhat closely-fitting mantel of thin black cardboard, we observe in a completely-darkened room that a paper screen washed with barium-platino-cyanide lights up brilliantly and fluoresces equally well whether the treated side or the other be turned towards the discharge tube. Fluorescence is still observable 2 metres away from the apparatus. It is easy to convince oneself that the cause of the fluorescence is the discharge apparatus and nothing else.

2. The most striking feature of this phenomenon is that an influence (*Agens*) capable of exciting brilliant fluorescence is able to pass through the black cardboard cover, which transmits none of the ultra-violet rays of th sun or of the electric arc, and one immediately inquires whether other bodies possess this property. It is soon discovered that all bodies are transparent to this influence, but in very different degrees. A few examples will suffice. Paper is very transparent;† the fluorescent screen held behind a bound volume of 1,000 pages still lighted up brightly; the printer's ink offered no perceptible obstacle. Fluorescence was also noted behind two packs of cards; a few cards held between apparatus and screen made no perceptible difference. A single sheet of tinfoil is scarcely noticeable; only after several layers have been laid one the top of each other is a shadow clearly visible on the screen. Thick blocks of wood are also transparent; fir planks 2cm. to 3cm. thick are but very slightly opaque. A film of aluminium about 15mm. thick weakens the effect very considerably, though it does not entirely destroy the fluorescence. Several centimetres of vulcanised india-rubber let the rays through.‡ Glass plates of the same thickness behave in a different way, according as they contain lead (flint glass) or not; the former are much less transparent than the latter. If the hand is held between the discharge tube and the screen, the dark shadow of the bones is visible within the slightly dark shadow of the hand. Water, bisulphide of carbon, and various other liquids behave in this respect as if they were very transparent. I was not able to determine whether water was more transparent than air. Behind plates of copper, silver, lead, gold, platinum, fluorescence is still clearly visible, but only when the plates are not too thick. Platinum 0·2mm. thick is transparent; silver and copper sheets may be decidedly thicker. Lead 1·5mm. thick is as good as opaque, and was on this account often made use of. A wooden rod of 20 × 20mm. cross-section, painted white, with lead paint on one side, behaves in a peculiar manner. When it is interposed between apparatus and screen it has almost no effect when the X-rays go through the rod parallel to the painted side, but it throws a dark shadow if the rays have to traverse the paint. Very similar to the metals themselves are their salts, whether solid or in solution.

3. These experimental results and others lead to the conclusion that the transparency of different substances of the same thickness is mainly conditioned by their density; no other property is in the least comparable with this.

The following experiments, however, show that density is not altogether alone in its influence. I experimented on the transparency of nearly the same thickness of glass, aluminium, calcspar and quartz. The density of these substances is nearly the same, and yet it was quite evident that the spar was decidedly less transparent than the other bodies, which were very much like each other in their behaviour. I have not observed calcspar fluoresce in a manner comparable with glass.

4. With increasing thickness all bodies become less transparent. In order to find a law connecting transparency with thickness, I made some photographic observations, the photographic plate being partly covered with an increasing number of sheets of tinfoil. Photometric measurements will be undertaken when I am in possession of a suitable photometer.

5. Sheets of platinum, lead, zinc and aluminium were rolled until they appeared to be of almost equal transparency. The following table gives the thicknesses in millimetres, the thicknesses relative to the platinum sheet, and the density:—

Thickness.	Relative thickness.	Density.
Pt. 0·018	1	21·5
Pb. 0·05	3	11·3
Zn. 0·10	6	7·1
Al. 3·5	200	2·6

It is to be observed in connection with these figures that although the product of the thickness into the density may be the same, it does not in any way follow that the transparency of the different metals is the same. The transparency increases at a greater rate than this product decreases.

6. The fluorescence of barium-platino-cyanide is not the only recognisable phenomenon due to X-rays. It may be observed, first of all, that other bodies fluoresce—for example, phosphorus, calcium compounds, uranium glass, ordinary glass, calcspar, rock salt, &c.

Of especial interest in many ways is the fact that photographic dry plates show themselves susceptible to X-rays. We are thus in a position to corroborate many phenomena in which mistakes are easy, and I have, whenever possible, controlled each important ocular observation on fluorescence by means of photography. Owing to the property possessed by the rays of passing almost without any absorption through thin sheets of wood, paper, or tinfoil, we can take the impressions on the photographic plate inside the camera or paper cover whilst in a well-lit room. In former days this property of the ray only showed itself in the necessity under which we lay of not keeping undeveloped plates, wrapped in the usual paper and board, for any length of time, in the vicinity of discharge tubes. It is still open to question whether the chemical effect on the silver salts of photographic plates is exercised directly by the X-rays. It is possible that this effect is due to the fluorescent light which, as mentioned above, may be generated on the glass plate or perhaps on the layer of gelatin. "Films" may be used just as well as glass plates.

I have not as yet experimentally proved that the X-rays are able to cause thermal effects, but we may very well take their existence as probable, since it is proved that the fluorescent phenomenon alters the properties of X-rays, and it is certain that all the incident X-rays do not leave the bodies as such.

The retina of the eye is not susceptible to these rays. An eye brought close up to the discharge apparatus perceives nothing, although, according to experiments made, the media contained in the eye are fairly transparent.

7. As soon as I had determined the transparency of different substances of various thicknesses I hastened to ascertain how the X-rays behaved when passed through a prism—whether they were refracted or no. Water and carbon disulphide in prisms of about 30deg. refractive angle showed neither with the fluorescing screen nor with the photographic plate any sign of refraction. For purposes of comparison the refraction of light rays was observed under the same conditions; the refracted images on the plate were respectively about 10mm. and 20mm. from the non-refracted one. With an aluminium and a vulcanised-rubber prism of 30deg. angle I have obtained images on photographic plates in which one may perhaps see refraction. But the matter is very uncertain, and even if refraction exist it is so small that the refractive index of the X-ray for the above materials can only be, at the highest, 1·05. Using the

* Preliminary Communication to the Würzburg Physico-Medical Society. Published by Messrs. Stahel, of Würzburg, who will shortly also issue an English edition.

† By the "transparency" of a body I denote the ratio of the brightness of a fluorescent screen held right behind the body in question to the brightness of the same screen under exactly the same conditions, but without the interposing body.

‡ For brevity's sake I should like to use the expression "rays," and to distinguish these from other rays I will call them "X-rays."

Digitized by Google

fluorescent screen, I was unable to discover any refraction at all in the case of the aluminium and the rubber prism.

Researches with prisms of denser metals have yielded up to now no certain results, on account of the small transparency and consequently lessened intensity of the transmitted ray.

In view of this state of things, and the importance of the question whether X-rays are refracted on passing from one medium to another, it is very satisfactory that this question can be attacked in another way than by means of prisms. Finely-powdered substances in sufficient thicknesses only allow a very little of the incident light to pass through, and that is dispersed by refraction and reflection. Now, powdered substances are quite as transparent to X-rays as are solid bodies of equal mass. Hence it is proved that refraction and regular reflection do not exist to a noticeable degree. The experiments were carried out with finely-powdered rock salt, with pulverulent electrolytic silver, and with the zinc powder much used in chemical work. In no case was any difference observed between the transparency of the powdered and solid substance, either when using the fluorescent screen or the photographic plate.

It follows from what has been said that the X-rays cannot be concentrated by lenses; a large vulcanised-rubber and glass lense were without influence. The shadow of a round rod is darker in the middle than at the edge; that of a tube filled with any substance more transparent than the material of the tube is lighter in the middle than at the edge.

8. The question of the reflection of the X-rays is settled in one's mind by the preceding paragraphs, and no appreciable regular reflection of the rays from the substances experimented with need be looked for. Other investigations, which I will describe here, lead to the same result. Nevertheless, an observation must be mentioned which at first sight appears to contradict the above statement. I exposed a photographic plate to the X-rays, protected against light rays by black paper, the glass side being directed towards the discharge tube. The sensitive layer was nearly covered, star-fashion, with blanks of platinum, lead, zinc, and aluminium. On developing the negative it was clearly noticeable that the blackening under the platinum, lead, and especially under the zinc, was greater than in other places. The aluminium had exercised hardly any effect. It appeared, therefore, that the three above-mentioned metals had reflected the rays. Nevertheless, other causes for the greater blackening were thinkable, and in order to make sure I made a second experiment, and laid a piece of thin aluminium, which is opaque to ultra-violet rays though very transparent to X-rays, between the sensitive layers and the metal blanks. As again much the same result was found, a reflection of X-rays by the above-mentioned metals was demonstrated. But if we connect these facts with the observation that powders are quite as transparent as solid bodies, and that, moreover, bodies with rough surfaces are, in regard to the transmission of X-rays, as well as in the experiment just described, the same as polished bodies, one comes to the conclusion that regular reflection, as already stated, does not exist, but that the bodies behaved to the X-rays as muddy media do to light.

Again, as I could discover no refraction at the point of passage from one medium to another, it would seem as if the X-rays went through all substances at the same speed, and that in a medium which is everywhere, and in which the material particles are embedded; the particles obstructing the propagation of the X-rays in proportion to the density of the bodies.

9. Hence it may be that the arrangement of the particles in the bodies influence the transparency; that, for example, equal thicknesses of calcspar would exhibit different transparencies according as the rays were in the direction of the axis or at right angles to it. Researches with calcspar and quartz have yielded a negative result.

10. It is well known that Lenard, in his beautiful investigation on Hittorf cathode rays passed through thin aluminium foil, came to the conclusion that these rays were actions in the ether, and that they pass diffusively through all bodies. I have been able to say the same about my rays.

In his last work Lenard has determined the absorption coefficient of various bodies for cathode rays, and amongst other things for air atmospheric pressure at 4·1, 3·4, 3·1, at per centimetre, and found it connected with the exhaustion of the gas contained in the discharge apparatus. In order to estimate the discharge pressure by the spark-gap method, I used in my researches almost always the same exhaustion. I succeeded with a Weber photometer (I do not possess a better one) in comparing the intensity of the light of my fluorescing screen at distances of about 100mm. and 200mm. from the discharge apparatus, and found in the case of three tests agreeing well with one another that it varied very nearly inversely as the square of the distance of the screen from the discharge apparatus. Hence the air absorbs a very much smaller fraction of the X-rays than of the cathode rays. This result is also quite in agreement with the result previously mentioned, that the fluorescing light was still observable at a distance of 2 metres from the discharge apparatus.

Other bodies behave generally like air—that is to say, they are more transparent for X-rays than for cathode rays.

11. A further noteworthy difference in the behaviour of cathode rays and X-rays consists in the fact that, in spite of many attempts, I have not succeeded, even with very strong magnetic fields, in deflecting X-rays by a magnet. The magnetic deflection has been up to now a characteristic mark of the cathode ray; it was, indeed, noticed by Hertz and Lenard that there were different kinds of cathode rays "distinguishable from one another by their phosphorescing powers, absorption and magnetic deflection," but a considerable deflection was nevertheless observed in all cases, and I do not think this characteristic will be given up without overwhelming evidence.

12. After experiments bearing specially on this question it is certain that the spot on the wall of the discharge apparatus which fluoresces most decidedly must be regarded as the principal point of the radiation of the X-rays in all directions. The X-rays thus start from the point at which, according to the researches of different investigators, the cathode rays impinge upon the wall of the glass tube. If one deflects the cathode rays within the apparatus by a magnet it is found that the X-rays are emitted from another spot—that is to say, from the new termination of the cathode stream.

On this account, also, the X-rays, which are not deflected, can not merely be unaltered reflected cathode rays passing through the glass wall. The greater density of the glass outside the discharge tube cannot, according to Lenard, be made responsible for the great difference in the "deflectability."

I therefore come to the conclusion that the X-rays are not identical with the cathode rays, but that they are generated by the cathode rays at the glass wall of the discharge apparatus.

13. This excitation does not only take place in glass, but also in aluminium, as I was able to ascertain with an apparatus closed by a sheet of aluminium 2mm. thick. Other substances will be studied later on.

14. The justification for giving the name of "rays" to the influence emanating from the wall of the discharge apparatus depends partly on the very regular shadows which they form when one interposes more or less transparent bodies between the apparatus and the fluorescing screen or photographic plate. Many such shadow-pictures, the formation of which possesses a special charm, have I observed some photographically. For example, I possess photographs of the shadow of the profile of the door separating the room in which was the discharge apparatus from the room in which was the photographic plate; also photographs of the shadows of the bones of the hand, of the shadow of a wire wound on a wooden spool, of a weight enclosed in a small box, of a compass in which the magnetic needle is completely surrounded by metal, of a piece of metal the lack of homogeneity of which was brought out by the X-rays, &c.

To show the rectilinear propagation of the X-rays there is a pin-hole photograph, which I was able to take by means of the discharge-apparatus covered with black paper. The image is weak, but unmistakably correct.

15. I looked very carefully for interference phenomena with X-rays, but unfortunately, perhaps only on account of the small intensity of the rays, without success.

16. Researches to determine whether electrostatic forces affect X-rays in any way have been begun, but are not completed.

Digitized by Google

17. If we ask what X-rays, which certainly cannot be cathode rays, really are, we are led at first sight, owing to their powerful fluorescing and chemical properties, to think of ultra-violet light. But we immediately encounter serious objections. If X-rays be in reality ultra-violet light this light must possess the following characteristics:—

(*a*) It must show no perceptible refraction on passing from air into water, bisulphide of carbon, aluminium, rock-salt, glass, zinc, &c.

(*b*) It must not be regularly reflected to any appreciable extent from the above bodies.

(*c*) It must not be polarisable by the usual means.

(*d*) Its absorption must not be influenced by any of the properties of substances to the same extent as it is by their density.

In other words, we must assume that *these* ultra-violet rays behave in quite a different manner to any infra-red, visible, or ultra-violet rays hitherto known. I could not bring myself to this conclusion, and I have, therefore, sought another explanation.

There seems at least some connection between the new rays and light rays in the shadow pictures, and in the fluorescing and chemical activity of both kinds of rays. Now, it has been long known that besides the transverse light vibrations, longitudinal vibrations might take place in the ether, and according to the view of different physicists *must* take place. Certainly their existence has not up till now been made evident, and their properties have not on that account been experimentally investigated.

May not the new rays be due to longitudinal vibrations in the ether?

I must admit that I have put more and more faith in this idea in the course of my research, and it behoves me therefore to announce my suspicion, although I know well that this explanation requires further corroboration.

LONGITUDINAL LIGHT.*

BY G. JAUMANN.

In a Paper published in 1888,† a law of discharges was enunciated, which has lately received striking confirmation, and which leads to important conclusions regarding the direction of vibration of cathode rays and light rays. Jaumann's law ran as follows: "Vibrations of electric force, taking place at an electrode, and in a direction normal to it, have a specific favourable effect upon the discharge; but, in order to be perceptible, their amplitude must increase with their period. To a first approximation, the effect is proportional to the product of the amplitude into the vibration frequency, or, in other words, to the maximum rate of change of the electric force during the vibration. Since only such vibrations as take place perpendicularly to the surface of the electrode have any effect, the orientation of the source is of considerable influence. This has been verified by Wanka in the case of electric waves, and by Elster and Geitel in the case of light.‡

The arguments in favour of the view that the cathode rays are longitudinal electric oscillations are the following: In the first place, the cathode rays are strongest in the axis of symmetry of the discharge space. Their intensity is greatest there, and decreases outwards. Hence they are essentially longitudinal, although a radial or tangential transversality may be superposed.

The existence of longitudinal electric waves is not admitted by the Maxwell-Hertzian equations. But almost any change whatever made in them makes their existence possible. Now rarefied air has such a peculiar behaviour towards electric discharges that Maxwell's equations cannot possibly be regarded as adequate. The very fact of discharge contradicts them.

Experiments concerning the influence of the conducting wires upon cathode rays show that their vibration period is of the same order of magnitude as the waves in the wires—*i.e.*, something between 10^{-8} and 10^{-9} seconds. Hence they are not ultra-violet rays. If they were transverse, without being ultra-violet, they would be ordinary light or Hertzian waves. From these they are distinguished, however, by their totally different properties.

But the longitudinal nature of cathode rays may be proved by actual experiments, which have already been performed by Lenard. They were shown to have strong discharging influence when impinging normally upon the surface of the electrode. *Hence their direction of vibration coincides with their direction of propagation.*

Rarefied air has many peculiarities owing to its small capacity for heat *and other forms of energy*. The peculiar electric behaviour of air is due to the fact that electric actions indirectly change its magnetic and electric constants. But as soon as μ and k are made variable in Maxwell's equations, longitudinal waves become possible.

The author works out new equations in accordance with these conditions, from which the existence of longitudinal rays follows as a matter of course. He also explains many of the peculiarities of discharge phenomena, such as the diffuse reflection of cathode rays by a plane smooth surface. This is due to the fact that Huyghens' principle becomes inapplicable when the direction of the cathode rays does not coincide with that of the statical electric force. He also explains the curvature of cathode rays in a magnetic field, and foreshadows the possible discovery of magnetic longitudinal waves. Herr Jaumann next shows that a limited cathode ray contains no transverse components along its axis, but that a radial electric and a tangential magnetic vibration sets in away from the axis, displaced by a quarter of a wave length from the original vibration. Conversely, he shows that transverse rays must always be blurred at the edges, and that even in ordinary air *longitudinal light, displaced by a quarter period, exists at the border of every pencil of transverse light.* This theoretical conclusion is completely substantiated by Elster and Geitel's work on the influence of the azimuth and angle of incidence of light upon liquid electrodes.* In rarefied air the amplitude of the longitudinal vibration is about one-third of that of the transverse vibration.

THE BERRENBERG-CHAPLIN VACUUM PUMP.†

I.—Description of the Pump.

This pump consists essentially (*see* Figs. 1, 2 and 3) of a cylinder having an air inlet near its lower end, and having within it two pistons, working the one within the other, each independently actuated by its own power piston. The action of these pistons is as follows:—

(*a*) They begin moving upwards from the bottom of the lower cylinder (Fig. 1) together, whereupon the air inlet A I is immediately uncovered by the outer piston O P, and the air contained in the lamps and connecting pipes expands into the pump cylinder.

(*b*) Having completed its upstroke (position shown in Fig. 2), the outer piston O P descends, the inner piston I P (dead black in the sketches) still ascending, until the two meet (position shown in Fig. 3), then the outer piston having closed the air inlet, the two pistons descend together for about one inch, until the outer piston rests on the bottom of the cylinder.

(*c*) The outer piston O P now remains at rest, while the inner piston I P continues its down stroke, forcing the air expanded into the cylinder during the up or suction stroke, through the valve V^1, and the oil filling the body of the piston and the holes H, into the space S^1, between the inner and outer piston heads.

The inner piston having completed its down stroke (position shown in Fig. 1), the motions begin again with (*a*), and, during the succeeding cycles, it will be seen that the air from the lamps, after being drawn into the cylinder and forced into the spaces S^1, is pushed through the valves V^2 in the outer piston head, into the upper part S^2 (Figs. 1 and 3) of the pump cylinder, whence it is driven by the upstroke of the outer piston through the valves V^3

* See *The Electrician*, June 21, 1895, Vol. XXXV., p. 272.
† Report by Prof. W. E. Ayrton, F.R.S., to the Langhans-Berrenberg-Chaplin Patents (Limited).

Digitized by Google

into the chamber Ch. From the chamber the air exhausts into the atmosphere through the outlet E.

The movements of the pistons, as described above, are given them by the power pistons, P P^1 and P P^2 (Fig. 1) working in the hydraulic cylinders, H C^1 and H C^2 respectively. Oil, under pressure given it by suitable centrifugal or other pumps, is let into these hydraulic cylinders, alternately above and below the power pistons, through rotary valves so made and geared together as to give the requisite movements to the pump pistons.

Examination of the Patent Specifications.—I have examined the Patent Specification No. 11,377, June 12, 1894, and the United States Patent No. 521,432, June 12, 1894, which contain the full description of, and the claims made for, the pump briefly described above, and I have compared them with the following specifications, which were handed to me as the result of a search made at the Patent Office by G. G. M. Hardingham, patent agent, viz. :—"Johnson's (Postle's) Blue Book," No. 3,792, 1876; "Lake's (Burnham's) Blue Book," No. 3,670, 1881; "Haddan's (Reis's) Blue Book," No. 5,688, 1883; "Gubbin's Blue Book," No. 515, 1886; "Lake's (John Patten's Manufacturing Company's) Blue Book," No. 7,426, 1890. At the suggestion of Mr. Hardingham, I have also examined the following specifications, viz., No. 4,716, 1883; No. 16,986, 1887; No. 12,690, 1889; No. 3,377, 1891; No. 12,686, 1892; and the United States Patent, No. 221,201, 1879.

FIG. 3.

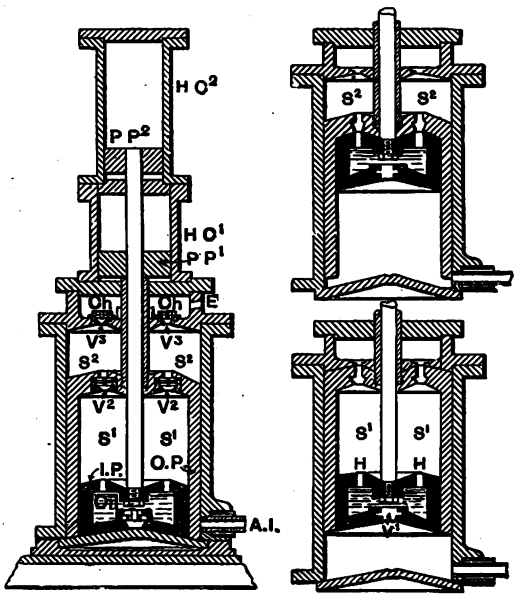

FIG. 1. FIG. 2.

A.I., Air Inlet. O.P., Outer Piston. I.P., Inner Piston. E, Exhaust. V^1 V^2 V^3, Valves. H H, Holes. P P^1 and P P^2, Power Pistons. H C^1 and H C^2, Hydraulic Cylinders. S^1 S^2, Spaces. Ch, Exhaust Chamber.

As the result of a complete examination of these specifications, and comparison of them with Chaplin's specification for improvements in vacuum pumps, I am of opinion that the claim for the "employment of two pistons, one working within the other, the outer one performing the function of a piston, of a cylinder and of a controlling valve," is valid, and has not been anticipated.

II.—The Practical Value of the Pumps Erected at No. 4, Huggin Lane.

Description of the Pumps.—The plant for exhausting incandescent lamps set up at No. 4, Huggin-lane, Queen Victoria-street, consists of two pumps on a common base, each containing two pistons, and working as described in Part I. of this report. While the one pump is drawing air into its cylinder from the lamps the other is discharging the air drawn in by it during previous upstrokes. By this arrangement a continuous expansion of air from the lamps into the pumps is maintained. These two pumps working alternately as described from what is called the "main" pump. As already explained, the air pistons of this main pump are connected with power pistons, working in hydraulic cylinders, and driven by oil under pressure. These hydraulic cylinders are connected with two accumulators, which store up the oil for that part of the cycle during which the pistons are at rest. The chambers above the cylinder heads (Ch. in Fig. 1), which receive the air after it has been exhausted from the lamps, are not, as indicated in the specification, open to the outside air, but are connected with an auxiliary pump which maintains a partial vacuum in them. Thus the main pump does not exhaust *into* atmospheric pressure, and neither does it exhaust *from* atmospheric pressure, for in practice the lamps are partially exhausted by the auxiliary pump before they are brought to the main pump. The function of the main pump is therefore confined to perfecting a partial vacuum by drawing the residue of the air into its cylinders and forcing it into spaces in which a partial vacuum is maintained by an auxiliary pump.

This auxiliary pump, which is called the "tank" pump, consists of four cylinders, each with an air inlet in the middle of its side, and containing a single cup-shaped piston. The four cylinders are placed in a tank and surrounded with oil. Air from the vessel to be exhausted expands into two of these cylinders, whence it is discharged into the remaining two, which in turn discharge it into the atmosphere. The last two cylinders also maintain a partial vacuum on the top of the oil in the tank, so that any air which may leak into it is drawn off.

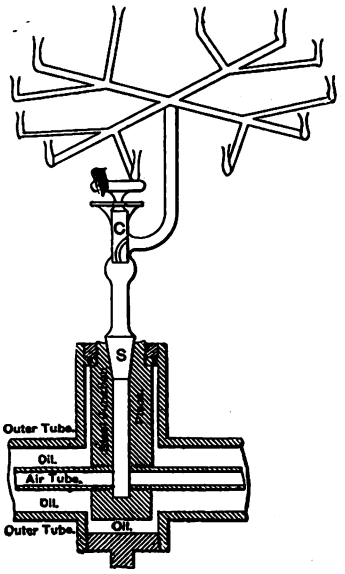

FIG. 4.

When exhausting lamps in practice they are blown in batches on to glass pieces shaped somewhat like the one sketched in Fig. 4. The lower ends S of these glass pieces are ground into stoppers, and the upper and lower parts are divided from each other by stop-cocks C. These stoppers are placed in a lamp rack connected with the tank pump, and after a partial vacuum has been produced in the lamps the stop-cocks C are closed, and the lamps are transferred to a system of pipes in connection with the main pump.

This system of pipes, a sketch of which is given in Fig. 5, consists of a main pipe which leads through a stop-cock, *a*, to the cylinders of the main pump, and six branch pipes (1, 2, 3, 4, 5, and 6 in Fig. 5), which can be separated from the main pipe by closing stop-cocks *b*, *c*, *d*, *e*, *f* and *g*. All these pipes are *double*,

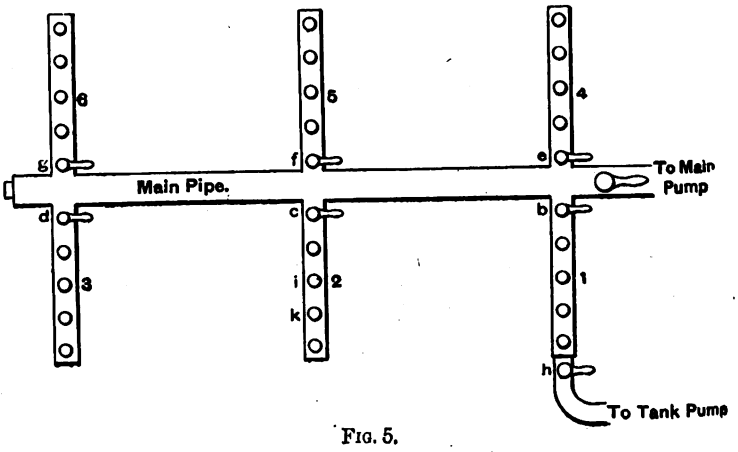

FIG. 5.

consisting of a brass inner air pipe and a cast-iron outer pipe, the space between the two being filled with a special oil which renders all the inner tubing perfectly airtight. Any air which may leak through the outer pipe into the oil is sucked out by the tank pump, so that none of it is able to leak through the *inner* pipe into the lamps.

In each of the branch pipes there are four junction boxes (Fig. 4) containing conical holes leading into the inner air pipes. In these holes are placed the ground ends, S, of the glass pieces carrying batches of lamps. Within these lamps, as explained above, a partial vacuum held by the glass stop cocks, C, has been produced

Digitized by Google

by the tank pump. The sketch in Fig. 4 shows how these ground ends fit into the conical holes, and the way in which the junction pieces are made and surrounded with oil. The glass stoppers are ground on a machine, so as to be perfectly alike and interchangeable, and the joints are greased with a special mixture of Russian deer tallow and beeswax and may be finally sealed with a little oil.

Method of Testing Pumps.—For the purposes of my tests 14 glass bulbs, shaped as in Fig. 6, and having a capacity, as measured by me, about equal to that of 15 lamps, and five bulbs having a capacity about equal to that of 11 lamps, were blown on to glass stoppers (S in Fig. 6) and placed in the junction boxes in the branches 2, 3, 4, 5 and 6 in Fig. 5. The total capacity of the bulbs on the pumps was therefore about equal to that of 265 lamps.

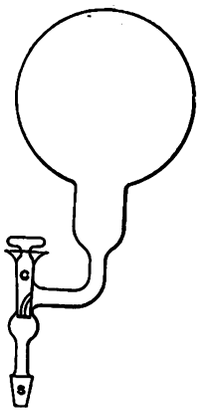

Fig. 6.

For measuring the pressure of the vacua produced by the pumps, I used the McLeod gauge, sketched in Fig. 7. This gauge consists of a glass bulb B, terminating in a capillary tube C, closed to the air at the top, blown on to the glass tube P, to the lower end of which a glass vessel M, containing mercury, is attached by a rubber tube. The upper end of the tube P is ground into a stopper S, which was fixed in the junction box *i*, in branch pipe 2 (Fig. 5). When it was desired to measure the pressure of the vacuum produced by the pump in the gauge, the vessel M was raised, and the mercury rising past the opening *a*, closed the little floating valve V, and compressed the air in B into the capillary tube C. The length of the tube occupied by the compressed air when the mercury was at the same level in the vessel M as in the capillary

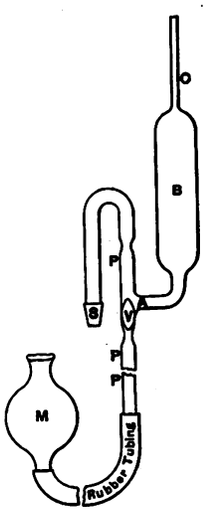

Fig. 7.

tube C, was a measure of the pressure of the vacuum. The sensibility of this McLeod gauge was stated by the makers, Messrs. Cetti, to be such that 1mm. remaining in the capillary tube after the mercury had been raised indicated that the pressure had been reduced to 1/500,000th of the atmospheric pressure. It was, of course, impossible to test the exact accuracy of this figure without entirely dismantling the gauge. I made, however, some rough measurements which showed that the number was, if anything, too large rather than too small. Hence, by using the figure 1/500,000 to determine the pressure of the air remaining in the lamps from my readings of the gauge, the performance of the pump is under rather than over-estimated.

As explained above, in practice the lamps are partially exhausted by the tank pump *before* they are placed on the system of pipes in connection with the main pump; but as it had not been thought necessary to erect in Huggin-lane a rack on which the partial vacuum could be made, and as the pump does not work to its best advantage when exhausting from ordinary atmospheric pressure, a pipe was, at my suggestion, brought from the tank pump and connected with branch pipe 1 (Fig. 5) through a temporary stop-cock *h*. By this means both the partial and the final exhaustion could be done with the bulbs in position on the system of oil jacketed pipes, the method of proceeding being as follows:—

The main pump was shut off from the system by closing the stop-cock *a* (Fig. 5), and all the cocks *b*, *c*, *d*, *e*, *f* and *g* were opened, and then by opening the cock *h* the tank pump was connected with the bulbs, in which it produced a partial vacuum. When this had been done the tank pump was disconnected from the system by turning off the cocks *h* and *b*, and then cock *a* was opened to enable the main pump to complete the exhaustion.

Vacua obtained.—On the afternoon of Friday, December 13, 1895, the following tests were made: The tank was started at 2.48 p.m., and 2½ minutes later the main pump was started. At 2.53 p.m., or five minutes from the starting of the tank pump, the cocks *b* and *h* (Fig. 5) were opened. After two minutes a partial vacuum having been produced in the pipes and bulbs, the tank pump was isolated from the system by closing the cocks *b* and *h*, and the cock *a* leading to the main pump was opened. After 15 minutes pumping the McLeod gauge read 2mm., showing that the pressure in the bulbs was but 1/250,000th of an atmosphere; after 20 minutes pumping the gauge read 1mm., and 1 minute later, under 1mm., proving that the pressure had been reduced to less than 1/500,000th part of an atmosphere. The stop cock at *a* (Fig. 5) was now shut and that at *b* opened, and air let into the system by taking out one of the stoppers in branch pipe 1. The glass stopper having been

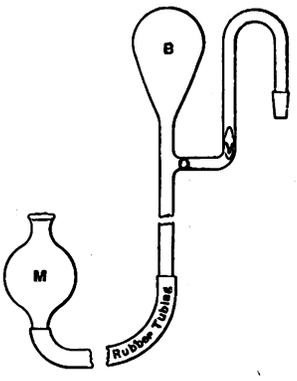

Fig. 8.

replaced, a partial vacuum was produced for 1½ minutes by the tank pump, which was then turned off and the main pump turned on. Readings, the results of which are shown in the following table, were taken with the McLeod gauge at intervals.

Time for turning on the main pump.	Reading of McLeod gauge.	Approximate pressure in atmospheres.
5 min.	13 mm.	13/500,000
9½ min.	4½ mm.	1/111,111
14 min.	3 mm.	1/166,666
16½ min.	2½ mm.	1/200,000

Comparison with Vacua in Commercial Lamps.—With the object of comparing the vacua I was obtaining with those found in commercial lamps, the gauge sketched in Fig. 8 was put in junction box *k* (Fig. 5). In this gauge the vacuum is produced in the lamp bulb B, and on lifting the vessel M, mercury rises past the opening O, and compresses the air in the bulb into a bubble at the top. By comparing the size of this bubble with the size of that obtained when an ordinary commercial lamp is broken under mercury a comparison could be made between the vacuum created with the pump under test, and the vacuum created by the pumps used in the manufacture of the glow lamps examined.

After putting the new gauge in position, and after producing a partial vacuum with the tank pump, the main pump was turned on and the following results were obtained:—

Time from starting the main pump.	Reading on McLeod gauge.	Approximate pressure in atmospheres.	Approximate diameter of air bubble in lamp bulb.
2⅔ min.	5·5mm.	1/90,900	0·1in.
15 min.	2·0mm.	1/250,000	0·06in.
21 min.	1·5mm.	1/333,000	0·03in.

Digitized by Google

To obtain the comparison required I had broken under mercury eight glow lamps of two well-known makes. Of these lamps one gave a bubble of air of about 0·12in. in diameter, four gave bubbles having diameters of the order 0·06in., and three gave bubbles varying in diameter from 0·25in. to 0·5in.

From these results it will be seen that the pump produced in 21min. a better vacuum than that found in any of the eight commercial lamps extended.

Facility with which the Glass Joints can be Made.—To test whether or no there was any difficulty in making the glass joints airtight, my assistant, Mr. Medley, took one of the bulbs out of its junction box and removed from its connecting tube the glass stop-cock (C in Fig. 6). He then regreased the cock and stopper, and replaced them in their respective positions. The tank pump was then used for one minute to create a partial vacuum, after which the main pump was turned on, with the following results :—

Time from starting the main pump.	Reading on McLeod gauge.	Approximate pressure in atmospheres.	Approximate diameter of air bubble in lamp bulb gauge.
5min.	14mm.	1/35,700	0·18in.
15min.	5mm.	1/100,000	0·08in.
21min.	1·5mm.	1/333,000	0·03in.

Pumping against a Leak.—As explained above, the tank pump was connected with branch pipe 1 (Fig. 5) through a temporary cock *h*; when both the pumps were off, this cock, which was *not* jacketed with oil, leaked sufficiently to reduce the readings on the McLeod gauge from 40mm. to 60mm., or by about 1/25,000th of an atmosphere, in 6½sec. In order to test how good a vacuum the main pump could create when working against this leak, the cock *b* (Fig. 5) was left open, so that the air leaking in through *h* could get into the rest of the system. Working under this condition the main pump was able to produce a vacuum of about 1/25,700th of an atmosphere, corresponding with an air bubble in the lamp-bulb gauge having a diameter of about 0·18in. This test, therefore, proved that even when working against a leak of some considerable size the main pump was able to create a fairly high vacuum, and also pointed to the necessity of there being a continuous oil jacket throughout the whole system.

Air-tightness of the Pipes, &c.—I thought it would be desirable to know whether, if a batch of lamps, in which a good vacuum had been created at the end of a working day, had to be left on the pipes during the night or possibly over a Sunday, it would be necessary to repump them when work was resumed.

On Saturday morning, December 14th, I therefore had the pipes and bulbs pumped out until the McLeod gauge read 3mm., corresponding with 3/500,000ths of an atmosphere. The stop-cocks, *a*, *b*, *c*, *d*, *e*, *f*, *g* and *h* (Fig. 5) were then closed to divide the system up into sections, the pumps were stopped and the latchkeys of No. 4, Huggin-lane were delivered up to Mr. Medley. On returning on Monday, December 16th, and testing the vacuum in branch pipe 2 (Fig. 5), it was found to be still as high as 6/500,000ths of an atmosphere. Air had, of course, leaked through the temporary stop-cock *h*, into branch 1, and a little had also leaked past the cock at *b* into the main pipe. The main pipe was, therefore, pumped out until it also showed a vacuum having a pressure of 6/500,000ths of an atmosphere. The pump was then turned off and the cocks *e*, *f*, *d* and *g* opened in succession, readings of the McLeod gauge being taken after each opening. The readings so obtained from the gauge were as follows :—

After opening cock.	Reading on the McLeod gauge.	Approximate pressure of vacuum in atmospheres.
e	8mm.	1/62,500
f	12mm	1/41,700
d	15mm.	1/33,000
g	15mm	1/33,000

After these cocks had all been opened a reading was taken on the lamp-bulb gauge, and it showed a bubble of air about 0·12in. in diameter.

Therefore, after the pumps had been stopped for some 46 hours, there was still in the branch pipes 2, 3, 4, 5 and 6 a good vacuum; and, although a little air had leaked through the cock *b* into the main pipe, it must be remembered that, owing to the leakage through the temporary cock *h*, the cock *b* had had to hold for many hours the difference of pressure between the full vacuum in the main pipe and the very partial vacuum in branch 1.

Effect of a Rush of Air into the Main Pump.—My next test was designed to answer the question as to whether the working of the main pump would be affected if an abnormal rush of air into its cylinders took place. Such a rush of air would occur if a batch of lamps while being exhausted was accidentally broken off its glass stem, or if a cock communicating with the atmosphere was accidentally opened. I had placed in one of the junction boxes in branch pipe 1 a glass stopper with a cock in it, as in Fig. 6, but open to the atmosphere above, so that the whole system could be opened to the air by turning the glass stop-cock C. After a good vacuum had been obtained, and while the main pump was still working, this glass stop-cock was twice opened, and air allowed to rush into the pipes, bulbs and cylinders. At the first trial the air was allowed to rush in for a rather longer time, and at the second trial for a much longer time, than was necessary to reach and turn off the stop cock *b* (Fig. 5), and so to shut off the supposed breakage from the rest of the system. After each opening the main pump reproduced a vacuum of about 3/500,000ths of an atmosphere in about 20min.

From these results it was clear that the working of the main pump was in no way affected by an abnormal rush of air into its cylinders, lasting for a time considerably longer than that necessary to reach and turn off one of the stop-cocks.

Conclusions.—As the results of these various tests, I am of opinion—

(1) That the combination of pumps as erected at No. 4, Huggin-lane, is capable, in 15min., of creating a vacuum as *good* as that in the best, and *much better* than that in the worst, of the glow lamps I examined; and that it is capable, in 20min., of creating a vacuum *much better* than that in *any* of the lamps I had broken under mercury.

(2) That the system of pipes, cocks and glass stoppers is, for all practical purposes, perfectly airtight.

(3) That even should a small leak occur, the pumps are able to work against it until it is remedied.

After an examination of the drawings for and the structure of the pumps at No. 4, Huggin-lane, I am also of opinion—

(4) That they are well and solidly constructed, and not liable to get out of order.

(5) That, owing to the absence of heat, the slow movements of the working parts, and the unusual quality of the lubrication (due to the continual passage of small quantities of oil through the pump), the wear of the rubbing surfaces will be very slight indeed.

MR. W. P. J. FAWCUS'S PRESIDENTIAL ADDRESS TO THE NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

[ABSTRACT.]

I must sincerely thank you for the honour you have done me by electing me your President. To follow in the footsteps of my predecessor, Mr. Edmunds, is no easy matter, but my connection with this Society from its commencement has been so intimate and my friendship with a large portion of the members is such that my task will be easier than it might otherwise have been.

In electric traction it is satisfactory to see the large number of schemes which are in the process of development or in course of construction; there is little doubt that in the course of a few years the majority of the tramways in this country will be worked by electricity. The vast superiority of electric power for this purpose over either horse, steam, or cable traction has been amply proved, at all events to the minds of all thoughtful electrical engineers, although no doubt much remains to be done in convincing many of our municipal authorities.

The stumbling blocks so far in the way of development in this direction have been the supposed unsightliness of overhead wires and the imaginary difficulties in the use of conduit systems. In the former case the objections have arisen from the temporary character of work of that kind in the States, but the excellently-arranged systems recently inaugurated at Bristol and Coventry have already gone far to remove these prejudices. And in the latter case the successful working of the new systems in operation in the United States and on the Continent, and the inventive efforts at present being devoted to the subject, will no doubt shortly remove this difficulty also. It is very satisfactory to note that at Leeds both overhead and conduit systems are to be installed. The use of electrical transmission of power, especially in large works, is increasing rapidly, and I have no doubt a large amount of work and I hope profit will come to the industry from this source.

A step of great importance to engineers, especially those having charge of continuous-current stations, is the introduction of high-voltage lamps. At the present time lamps are in use in several stations working at pressures of from 200 to 230 volts, and have proved themselves satisfactory when properly made. Those which have so far proved the best have two or more filaments arranged in series, no filament having to stand an abnormal pressure. Made in this manner it is possible to obtain a good lamp for 230 volts as

Digitized by Google

small as 8 c.p., while a lamp of 16 c.p. can be made to run with pressures up to 400 volts.

The possibility of obtaining lamps for such high voltages will no doubt induce engineers to gradually raise voltages within the premises of consumers; and here I should like to strike a note of warning. Although there may be no objection to using pressures up to 400 volts in public buildings or elsewhere when the installation is under experienced control, and the fittings are inacessible to the public, for private houses and ordinary business premises where the inexperienced cannot be prevented from having access to the wires and fittings, 200 to 230 volts is quite high enough for personal safety. Even if there is no actual danger to life from the direct effects of a shock of from 250 to 400 volts—a question which is open to doubt—the indirect results of such a shock might be most injurious or even fatal if received by a delicate person or one in a dangerous position. It would be an evil day for the industry if through the occurrence of fatal accidents to the general public that the electric light should again get the name of being dangerous, which, fortunately, it has now practically lived down.

There is another reason why considerable caution should be exercised in converting existing installations from low to high pressures: the types of switches and other fittings commonly in use are totally unsuited to pressures much beyond what they were designed for, and, in the case of some of the older installations, the insulation on the wires will be insufficient.

Attention has recently been drawn to the subject of life and efficiency of incandescent lamps by the tables and correspondence which have appeared in the technical papers on lamp tests. It is surprising how few of the public, or even of practical electrical engineers, take the trouble to learn anything about incandescent lamps, when by using a little knowledge easily acquired on this subject, it may often be to reduce the cost of lighting to one half. It is possible for the lamp manufacturer to produce to suit a variety of different conditions, provided he is made aware of them, but as he seldom is furnished with any particulars beyond the candle-power and volts at which the lamps will have to work.

He frequently has his lamps condemned as bad when in reality there is nothing the matter with them if used under proper conditions.

In certain cases it may be desirable for the consumer to use a lamp which, although working at a comparatively low efficiency, will keep its full candle-power during its life; lamps of this type can easily be procured.

In other cases it may be preferable, on account of the cost of energy, to use a lamp which will consume a minimum of current. In this case the consumer must be prepared to sacrifice either constancy of candle-power or duration of life; no lamp has so far been produced which combines a long life with high efficiency and constant candle-power. Again, it may be impossible to guarantee the regularity of the pressure at which the installation runs. Under these conditions an ordinary lamp would have a short life, but if the maker is made aware of them he can specially construct one suitable.

I have for the last few weeks been engaged on a series of experiments upon lamps of most of the leading English and Continental makers. During these experiments, one or two interesting points, which may not be known to all of you, have come under my notice.

I have observed in the case of many lamps, commencing their life with an efficiency of about 4 watts per candle-power (a very usual efficiency), that in the course of from 100 to 150 hours run the candle-power has increased as much as 20 to 30 per cent., and the watts from 15 to 25 per cent., and has then gradually fallen until the end of their life. Installers should bear this point in mind, as the use of such a lamp in an installation where the plant had not a fair margin of power might well lead to trouble through over-loading.

I have also observed that in some lamps commencing their life with an efficiency of from 2½ to 3 watts per candle-power, no rise, or at all events a very slight one, was observable in the candle-power at any period of their life, but a steady and fairly rapid fall from the commencement until a critical period is reached at between 300 and 500 hours, when the lamps reach almost their minimum efficiency from 4 to 4½ watts per candle-power, and continue in this state for the remainder of their life, which, in the case of some of the better lamps, has averaged considerably over 1,000 hours.

This would point to the advisability of using a high efficiency lamp as such for a time, and subsequently moving it to a less important position for the remainder of its life, being content with about its original light; it would then be no worse than an ordinary lamp of the lower candle-power.

I hope in the near future it may be possible for supply undertakings to sell light to their customers, and not current. For only in this way will it be to the advantage of the engineer—generally the only person competent to come to a just conclusion—to see that the current is being consumed by suitable and efficient apparatus.

It is somewhat an unsatisfactory sign that so much foreign material is being sold in this country, and is in many cases introduced and encouraged even by those who are striving in other branches of the industry to compete against it.

British electrical engineers are now entering on a critical period of their existence; they are being threatened on all hands by foreign competition, and unless they wish their business to get into the hands of the German, they must not only strive to keep up the high reputation which English workmanship has always possessed, but must be prepared to support one another by reciprocating business and refusing to buy abroad when it is possible to obtain as good an article at home.

THE INSTITUTION OF ELECTRIC AL ENGINEERS AND NATIONAL DEFENCE.

At the ordinary general meeting, held at the Institution of Civil Engineers, 25, Great George-street, on Thursday evening, January 16th, the retiring PRESIDENT (Mr. R. E. B. Crompton), after distributing the various premiums to the successful readers of Papers, said his last duty was to vacate the chair in favour of a better man. He did not think the choice of the Institution could have fallen on a more worthy man than Dr. Hopkinson, to whom they all owed so much, and who by his scientific work and by his practical contributions to their scientific knowledge of the dynamo, and by his careful studies of the properties of the materials that they used in the construction of electrical apparatus, had done more almost than any Englishman, or he might say more than any man in any country, to forward the great cause of electrical engineering. In conclusion, he could only say that he felt himself a proud man to be succeeded by such a great man.

Major-Gen. WEBBER said it was his unexpected but warmly-appreciated duty to ask the Institution and all their guests present that evening to agree with acclamation "That the cordial thanks of the Institution are due to Mr. Crompton for the energy and ability he has displayed in performing the duties of President during the past year." Of his energy and his efficiency those who had attended their meetings were fully aware, and therefore he would occupy none of their time in bringing home to them what they felt for themselves. But of his efficiency in the Council Chamber, and as Chairman of their committees, they could have very little knowledge, except from previous acquaintance with the energy, zeal and ability he had given to all the work he had undertaken during the many years that they had had the honour and pleasure of knowing him both as a friend and as a fellow engineer. To him (the speaker) this had been a red-letter year, having sat, as he had done, under Mr. Crompton in committees, for their late President's activity, constant attendance, and intimate acquaintance with detail had brought about results which he was glad to say would last through the history of their Institution. As Chairman of one committee in particular—one which came most readily to his mind—the Committee for the Revision of the Fire-Risk Rules—he showed a power of leadership and a power of direction and guidance which he (General Webber) had rarely seen exercised by any other Chairman under whom he had sat.

Mr. DANE SINCLAIR seconded the resolution, which was carried with acclamation, and briefly responded to by Mr. CROMPTON.

The PRESIDENT, who was loudly cheered, having taken his place in the chair, said that before delivering his Address he wished to say something with regard to a matter which intimately concerned the country. Recent events had made unpleasant revelations to many of them. They proved that among other peoples there were certain persons who would regard with satisfaction any danger that might befall us, and that the error of a few of our countrymen might be magnified by persons who did not like us, so as to involve us in quarrels with people we had always regarded as our friends. To provide against such danger was no Chauvinist or Jingo move. It threatened no one; it simply meant that they, as Englishmen, would not allow the evils that might result from the follies of their countrymen abroad to cause mischief at home. Continental nations met this and all other dangers by forcing military service on every able-bodied citizen. We hoped to attain the same object without compulsion. Surely it was the duty of every one of them to consider what they could personally contribute towards the nation's defence. And for such societies as theirs it was their duty to consider what action they could take in their corporate capacity to the same end. They had a number of past and present Royal Engineers on their roll. Electricity was put to innumerable uses in military operations at the present day — for the training and firing of guns and the firing of mines; for telegraphs, for signalling, for search lights. Their technical knowledge might be very useful indeed, and it could not be doubted that many of them would be glad to give their services. The question was, how it could be done, and what steps should be taken to do it. He knew certainly for a fact that anything they could do effectively would be welcomed heartily by the highest authorities in the Army. He had consulted some of their best-known members. He wrote to Lord Kelvin and asked him what he thought of the idea of utilising the qualifications of electrical engineers for purposes of national defence. Lord Kelvin cordially approved of it, and said he would be glad to do all he could to further the movement, from which he expected valuable results. Other distinguished electricians had agreed that such a movement would be eminently useful, and at the present moment would be likely to be successful. The Council of the Institution had passed a resolution that steps should be taken to render available for purposes of national

Digitized by Google

defence the technical skill of their members, and a Committee had been formed to consider the question, constituted as follows:—Dr. Hopkinson (president), Mr. Crompton, Mr. Henry Edmunds, Sir F. Abel, Mr. A. E. Mavor, and Mr. R. S. Erskine. Probably this Committee would first of all ascertain what members were willing to serve and what time they could give to training, and what places could be filled in existing corps. If they had more men than were necessary to fill these places a new corps might be formed. If each of them would do his duty according to his opportunities they would succeed in rendering valuable service to their country. The President then proceeded to the delivery of his Inaugural Address, which will be found in full elsewhere in the present issue.

LONDON COUNTY COUNCIL.

At the first meeting of the London County Council held at Spring-gardens after the Christmas recess, Sir Arthur Arnold presiding, it was reported that the chief officer of the Fire Brigade was of opinion that every effort should be made to encourage persons to place their premises in electric communication with fire stations, and with that idea he recommended that the annual charge now made for the privilege should be substantially reduced. The Committee had decided to reduce the charge to £2. 2s. a year, and wished attention to be called to the advantage to manufacturers and others of having their premises in direct communication with fire stations instead of relying on the public fire alarms. The order prohibiting the introduction of call bells had been revoked for the chief officer stated that there had recently been submitted to him a new form of fire alarm, by means of which an accidental ringing of the bell from contact of wires or other causes could at once be distinguished in a fire station from a proper call.

County Council Subways.

Mr. EMDEN moved: "That it be referred to the Highways Committee to consider and report without delay on the expediency of the Council applying to Parliament for power for the Council and the local authorities to construct subways under the streets of London, for the reception of the tubes and wires of the gas, water, electric and other companies, and to charge rents for the same." He pointed out the great loss that accrued to the ratepayers from the continual pulling up of the streets to lay electric, gas, and other tubes, and he contended that great advantage would be gained by the companies interested. Further, he thought the cost of construction and maintenance would be met by the rents which would be obtained for the use of the subways.

Major PROBYN seconded the motion.

Mr. JOHN BURNS thought none had a better right to bring forward such a motion than the representative of the Strand (Mr. Emden) for that district was treated in a scandalous manner by the electric lighting and other companies; but he thought the object sought would not be obtained unless there was some degree of compulsion exercised to make the companies use the subways.

Mr. CHARLES HARRISON suggested that the matter should also be referred to the Parliamentary Committee.

Mr. EMDEN accepted the suggestion, and the motion as amended was then carried.

Provisional Orders—Opposition.

The Highways Committee reported that three applications had been made to the Board of Trade for Electric Lighting Provisional Orders this sesison. Two of those were by the Vestries of Battersea and Newington as regarded their respective districts, and followed substantially the form in which Orders had been obtained by other local authorities, and appeared to require only very slight amendments. They recommended "That the Board of Trade be asked to insert in the Battersea and Newington Orders the amendments prepared by the Highways Committee." The third Order applied for by the County of London and Brush Provincial Electric Lighting Company, and entitled the County of London (South) Order, related to the St. Saviour's district and the parishes of Newington, Battersea, Lambeth and Camberwell. The district of St. Saviour's was already included in the areas referred to in the other two companies' Orders, the parish of Newington in one, parts of the parish of Lambeth in two (while the Vestry itself also had an Order), and the parish of Camberwell in two. The Vestry of Battersea strongly objected to the granting of the Order so far as related to that parish, and it appeared to the Committee that ample provision was made under previous Orders for the electric lighting in the district referred to in the Order now asked for. Accordingly they recommended that the Board of Trade be asked not accede to the application.

The recommendations were agreed to.

A Large Tramway Car House.—A car barn, said to be the largest in the world, has been built by the Brooklyn Heights Railroad Company. It has a floor area of 700ft. by 200ft., and is three storeys high. It serves as a depôt for six lines, and has a housing capacity of 1,000 cars. Each floor of the building has a direct entrance from the street, and therefore no elevators are required. Transfer tables at the front and rear of the barn assist in shifting the cars about. Well-equipped repairing shops are on the premises.

LEGAL AND POLICE INTELLIGENCE.

On Saturday and Monday last, at the Central Criminal Court, before the Common Sergeant, Edward Augustus Ingold, 30, engineer, and Alfred Attride, 34, horse trainer, were indicted for falsely applying to certain lamp holders a mark resembling the trade mark of the Edison and Swan United Electric Light Company, Limited, in such a manner as to be calculated to deceive.

Mr. C. Mathews and Mr. C. F. Gill prosecuted; Mr. Schulters Young defended Ingold, and Mr. Hurlton and Mr. Collison appeared for Attride.

In opening the case for the prosecution, Mr. MATHEWS referred to its importance to patentees generally, and said the facts which they had to inquire into ranged between August and November last. The prosecutors were the registered patentees of certain holders for electric lamps, in respect of which they had fixed a standard price as between themselves and those engaged in the manufacture of electric lamps. This was well known in the trade, and so far as the prisoner Ingold was concerned this fact would be brought home to him beyond the possibility of doubt. Ingold, as the jury would hear, was for some years in the employ of the Company as invoice clerk, but he left their service in January, 1892. He immediately afterwards went into the employment of a firm who were licensees for the manufacture of the holders. The jury would understand that the prosecutors, although they were patentees of the holders, granted licences to others in the trade upon conditions as to royalty, and also upon the undertaking that the holders should not be sold below a standard price. These licensees were allowed to stamp the holders they made as "Edison-Swan" patents, while the prosecutors stamped those they made "Ediswan." Both marks, however, were registered as trade marks, and Ingold particularly would be aware of the conditions under which the licensees were allowed to make the holders and as to the standard price. A copy of the conditions would be before the jury, and they would hear, as the case proceeded, that the holders so made by the licensees were to be of the best material and workmanship, and that they were not to be sold at a lower discount than 33 per cent., and, further, that the licensees were to pay to the prosecutors a royalty of 10 per cent. on the standard price. As he had before said, Ingold left the employment of the Company in January, 1892, and went into the employ of a firm of licensees of the prosecutors, and the jury would hear that in November, 1894, he got into communication with a Mr. Phillip James Cremer, of Cologne, who was a manufacturer on a large scale of electric lamp holders and other electrical accessories. Mr. Cremer appointed Ingold as his selling agent in England, and from that time until these proceedings were instituted Mr. Cremer became a victim of Ingold, as the large mass of correspondence which had been seized clearly showed that Ingold was putting forward a number of fictitious firms for the purpose of inducing the Cologne manufacturer to send over to this country very considerable quantities of electric lamp holders, for an object for which there could be no doubt when they came to consider the evidence. To this intent Ingold associated himself with one confederate after another for the purpose of getting their holders stamped with the Edison Swan trade mark, selling the holders at prices more profitable to him than if they had been obtained and stamped in the legitimate way. In the first instance he renewed his acquaintance with a man named Findley, who also had been in the employ of the Edison and Swan Company, and for the purpose of carrying out the unlawful purpose on which he had embarked, there was formed the firm of Findley and Co., of Walthamstow, who were described by Ingold to Mr. Cremer as electrical engineers and general railway contractors. Findley, no doubt, was as well aware of the rights and privileges of the licensees as Ingold himself. He also was aware of the fact as to the standard price, but Findley would be called as a witness for the prosecution, and he would tell the jury as to the holders which his firm obtained from Mr. Cremer. Then Ingold introduced Attride and Co. to Mr. Cremer. Attride was the man who stood by the side of Ingold in the dock, and Attride and Co. must, no doubt, be read as Ingold himself. Prior to this time the holders had been stamped with a genuine stamp belonging to the firm of Paterson and Cooper, who were licensees of the prosecutors. Unknown to Paterson and Cooper, one of their employees, a man named Cosgrave, who they would hear of hereafter, obtained possession of the stamp, with the cognisance, no doubt, of an overseer, who could not now be found, and he (Cosgrave) at his own house stamped large numbers of the holders. The matter came to the knowledge of Messrs. Paterson & Cooper, who promptly discharged both Cosgrave and the other man. In this difficulty it became necessary to resort to other means to get the holders stamped, and accordingly they would find Attride arranging with a worker of metal and die and stamp maker in St. Luke's, named Tucker, for the manufacture of the stamp "The Edison and Swan Patent" and for the stamping of the holders. In arranging with Tucker, Attride, as they would expect when a person embarked on a course of fraud of this character, did not give his correct name, but said he was James Ford, and that he lived at 22, Downham-road, Kingsland. This address was not a true one. Between October and the 1st inst. no fewer than 14 gross of these holders were stamped by Tucker. Attride took these holders to Tucker and fetched them away when stamped, and both Attride and Ingold were afterwards concerned in the disposal of them. Some of them were taken to the Electrical and General Engineering Company in Leadenhall-street, and the manager, Mr. Bowyer, would be called as a witness. He would state that Ingold told him that he was acquainted with a bailiff who had taken them for debt. On another occasion, when the manager was still curious as to how Ingold possessed himself of the holders, made a similar inquiry, and was told by Ingold that he was acquainted with a dealer who sometimes picked up job lots, and that thus he was enabled to sell the articles at below the standard price. This

Digitized by Google

part of the evidence would become of the greatest importance when the jury came to consider whether the mark on the holders was a colourable imitation of the prosecutor's trade mark, because they would find that Mr. Bowyer, in purchasing the holders, believed that he was purchasing the genuine article. Attride also would be connected with the sale of the holders to Mr. Bowyer. The matter was brought to the attention of the Edison and Swan Company, and they took steps to bring the matter home to the accused. They employed a man named Davis, who was known to Attride, and, acting under their instructions, Davis saw Attride and gave the latter six dozen holders to get stamped. Attride was followed and seen to take the holders to Tucker, who stamped them, and on Attride handing back the stamped holders he was arrested. He (Mr. Mathews) was at a loss to understand what the defence could be, for the evidence of Findley would be overwhelmingly corroborated, and if Ingold and Attride were engaged in honest transactions what was the need for all the secrecy which was observed by the accused. There was no doubt Ingold was the originator of this scheme, and he it is who introduced the various fictitious firms of Findley and Co., Attride and Co., Ryder and Co., Walters and Co., H. W. Walworth and Co., and so on to Mr. Cremer, who was induced to send large quantities of holders to this country under the pretence that the several firms were substantial business houses. The jury would judge of their substantiality when he mentioned, by way of illustration, that H. W. Walworth and Co., whose address was given as 18, Eldon-street, had no existence whatever, the address mentioned being a newsagent's, where letters and parcels were received. The other addresses were either newsagents or private houses, where Ingold could get possession of the holders. These holders, after being stamped, were left by the accused at cloak-rooms of railway stations, or at public-houses, until they could be disposed of. Ingold's private address in the Woodlands-road, Kilburn, was used as the address of one of the firms, and at the time of his arrest Ingold was negotiating with Mr. Cremer for the execution of an order from a very large Midland firm, whose business was of such a character that their name could not be disclosed, and who were to do all their business through Ingold, whose name alone was to be mentioned in the transaction. The jury, he thought, would have no difficulty in coming to a conclusion when they heard the evidence.

Witnesses were then called to substantiate counsel's statement, and Findley, in his evidence, stated that Ingold told him that he should wait until the bills of exchange, which had been given by the several firms ordering the goods, became due, when he should give information to the Edison and Swan Company and get £20, and should then "go." It was on hearing this that he (Findley) gave information to the prosecutors. In cross-examination Findley admitted that he expected £100 for his information.

Mr. HUTTON addressed the jury on behalf of Attride, urging that he had been the dupe of Ingold. He (Attride) was a rough rider at the Aquarium, and not a man of considerable proficiency in his profession.

The accused were both called as witnesses on their own behalf, and other evidence was called in defence.

Mr. SCHULTERS YOUNG, on behalf of Ingold, complained that the prosecution had taken criminal instead of civil proceedings. He denied that there was any trade mark in the words "Edison and Swan," and that, had civil proceedings been taken, Ingold was prepared to contest the registration of the trade mark. His case had been greatly prejudiced by his having been placed in the dock, and the prosecution hoped to crush a man by bought and tainted evidence.

Mr. GILL replied for the prosecution.

The COMMON SERJEANT in summing up the case for the jury, pointed out that the Act expressly provided that the imitation of trade mark need not be exact, but that it sufficed if the imitation was colourable and of such a character as to be calculated to deceive. It was suggested that the offence was created by the Trades Mark Act of 1887, but this was not so. The offence itself had always been an offence and a forgery at common law. Doubts however were created that these became more apparent after the case of Borwick's baking powder, in which a person made a mixture of his own in packets bearing the exact resemblance to those of Messrs. Borwicks. In 1862, the offence of doing this was made a statutory offence, and in 1887, when the Trades Marks Act was passed, the provisions of the Act of 1862 were repealed, but some of the most useful provisions of the Act of 1862, including this particular one, were re-enacted in the Act of 1887. They had nothing whatever to do with the matter of civil proceedings. The prosecutors were entitled to whichever remedy the law allowed them they liked; and the fact that they had taken criminal proceedings when they could have resorted to the Court of Chancery ought not to affect the minds of the jury one way or the other. No doubt the case of Ingold and Attride was entirely different. Attride might be the innocent agent it was stated that he was, but the evidence of Ingold alone threw considerable light upon his own guilt. According to his own showing he engaged Cosgrave through the other man employed by Messrs. Paterson and Cooper to stamp the holders with what he knew was the genuine stamp of the prosecutors' licensees. He therefore, according to his own showing, was engaged in a conspiracy with Cosgrave and the third man, Marsden, who could not now be found, to stamp the holders with the genuine stamp, the mark of which, the jury would bear in mind, was registered as a trade mark equally as well as was the trade mark "Ediswan." Had Ingold, as he said, simply desired to test the legality of the trade mark nothing could have been easier. He could have opened premises and notified the prosecutors of his intention, but he did nothing of the kind. On the contrary, the greatest secrecy was used in all the transactions. False names were used, and the holders, when stamped, were deposited at railway stations and other places until they could be sold. Then they had the untrue representations to Mr. Bowyer as to the manner in which Ingold had come by the holders. No better evidence as to the colourable imitation of the trademark could have been adduced than that given by Mr. Bowyer, because he, an experienced man, bought the holders believing that they were the genuine articles and that the trade mark upon them was that of the prosecuting firm.

The jury, without hesitation, found Ingold guilty and acquitted Attride.

The COMMON SERGEANT in discharging Attride, told him that he had acted most indiscreetly in the matter. He hoped this would be a caution to him against mixing himself up in a matter of this kind again. He (Attride) had much better follow his own legitimate business, in which he (the Common Sergeant) was told he was a man of considerable proficiency.

George Cosgrave, 22, engineer, then surrendered to his bail and pleaded guilty to a similar offence as that of which Ingold had been convicted.

Mr. CORNEY addressed the Court on behalf of Cosgrave, and as Mr. Mathews said the prosecution would be content if he were merely bound over, the Common Sergeant directed that he (Cosgrave) should enter into his own recognisances in £100 to come up for sentence if called upon.

No evidence was offered by the prosecution on the charge against Ingold of conspiring with Attride and defrauding the prosecutors of large sums of money, and a verdict of not guilty was returned.

Mr. MATHEWS said the prosecution regarded Ingold as the prime mover in this matter, and, as he had told them on his evidence, he had dealt very largely in these electric lamp holders, for he had confessed that some 13,000 of them had been delivered in London. In addition, he had ordered 3,000 more, and he was sending orders for 4,000 or 5,000 others. But this was not the worst feature of the case, because he had no doubt tempted the man Marsden who, prior to Ingold's acquaintance, had done honest service for the firm by whom he was employed. He had also been the means of bringing the man Cosgrave into the dock, and Attride also owed the position he had occupied during the trial to his connection with him. Therefore the case, so far as Ingold was concerned, was one of a very serious nature, for, having made himself familiar with the prosecutor's course of business, he had used his knowledge for an unlawful purpose.

The COMMON SERGEANT said Ingold had been engaged in the most mischievous and nefarious occupation, and the case could not have been proved against him by clearer evidence. He had no reason to believe that the forgery of trade marks was by any means a prevalent offence, or he should have dealt very differently with the accused than the manner in which he proposed to do. It was extremely desirable that the registration of trade marks should be protected, and he should sentence Ingold to nine months' imprisonment without hard labour.

Gulcher (New) Electric Light and Power Company v. Murray.

This case came before Mr. Justice Vaughan Williams, in the Chancery Division, on the 18th inst., for judgment. The case was referred to in our last issue. The facts of the case sufficiently appear in the judgment.

His LORDSHIP, in giving judgment, said that the question was whether Mr. Murray was liable to be put on the list of contributories in respect of 300 Preference shares in the Company. Mr. Murray was the holder of £300 in Debentures in the Company—Ten per Cent. Debentures—but in March, 1890, the Company was minded to raise a sum of some £37,000 by the issue of Ten per Cent. Preference shares, and it was proposed to use the money raised by the issue of those Preference shares to the extent of £16,000 in paying off those Ten per Cent. Debentures. It was intended that the whole of the £37,000 should not be called up in the first instance before 10s. in the £ was called up by instalments of 2s. 6d., the first being payable on application, and the last being payable some time at the end of August, 1890. Upon March 11th the Company seemed to have proceeded to allotment of those Preference shares. They seemed, after the manner of company promoters and company directors, to have made their allotment first and got their applications afterwards. In that state of things they, on March 11th, allotted Mr. Murray the 300 shares, and proceeded to send an allotment letter to him; but there had, apparently, been some conversation between Mr. Murray and Mr. De Castro, the chairman of the Gülcher Company. He (his Lordship) did not think that Mr. De Castro had filed any affidavit in the matter, for his attention had not been called to it—and the only affidavit as to the conversation was the affidavit of Mr. Murray. Judging from the subsequent conversations, he (his Lordship) had no doubt that Mr. Murray's account was true. Mr. Murray stated that he stipulated that he should not be called upon to accept any allotment unless and until 10s. in the £ were paid up on the 37,423 shares. Of course, Mr. De Castro, if he had accurately recollected what had passed between himself and Mr. Murray, had no right to make such statements to the Directors—if he did do so—as should induce them to allot in any other way except in accordance with the statement in that paragraph of the affidavit; but on March 17th Mr. De Castro wrote to Mr. Murray, saying: "I send you allotment letter with the condition you desire set out on the face of it." The allotment letter was dated, in print, March 13th, 1890. He supposed that most of those allotment letters were printed immediately after the allotment of March 11th. The letter stated that "his allotment has been made, conditional upon at least 10s. per share being paid up on 37,423 shares before you are called upon to pay up anything." On March 18th Mr. Murray wrote acknowledging the letter and stating that, providing the condition in the allotment letter was carried out, he would accept the shares. On March 19th Mr. De Castro wrote a letter to Mr. Murray which showed clearly that Mr. De Castro understood perfectly well Mr. Murray's letter of March 18th, and accepted it because the letter did not speak of it as a simple allotment but as an arrangement of which it was desirable to have a record. The application form was then forwarded. It was dated March 11th—which was, of course, untrue—and stated on it that the application was made on the terms of the Memorandum of Association and upon the special condition endorsed thereon, and then was set out that same condition which was set out on the face of the allotment. In his opinion the allotment letter was only intended to take effect upon

Digitized by Google

the happening of the particular condition endorsed upon it. When the end of August came it was admitted that this money had not been paid up on those other Preference shares. The Company was not in a position to carry out that which they had proposed to carry out. The result was that this arrangement, which was simply an arrangement under which Mr. Murray was to change his investment in the Company *pro tanto* from Debentures to Preference shares, was not carried through, because the company were not in a position to perform that condition. His Lordship then said that he found as a fact that Murray had no knowledge whatever of his name being on the register. In these circumstances he thought that Mr. Murray was not liable, and that the claim against him failed.

Mr. MARTELLI, who appeared for the respondent, asked that the application might be dismissed with costs.

His LORDSHIP said that he did not think that he ought to order the liquidator personally to pay the costs. If there were assets enough the respondent would get them.

Mr. GORE BROWN remarked that he thought that the assets would prove ample for such payment.

His LORDSHIP said that he always meant that the costs should be paid at once to the successful litigant where there were assets.

Mr. GORE BROWN replied that as this was the last incident in the winding-up, the time would be very short before they were paid, he was glad to say.

In re Woodhouse and Rawson, Limited.

This was an action before Mr. Justice Vaughan Williams, in the Chancery Division, on Friday last, on a summons taken out by the Official Receiver and Liquidator, asking leave under Section 10 of the Companies Acts to proceed against the Directors and Auditors of the Company.

Mr. HOWARD WRIGHT, who appeared as counsel for the Liquidator, reminded his Lordship that when the matter came before the Court on May 16th last the Court directed certain meetings to be held of the three classes of debenture holders to ascertain whether they desired to proceed or not. The result of that was that they decided not to proceed. Again the summons was adjourned to obtain the opinion of the debenture holders as to whether they would forego their claims on any sums recovered as the result of proceedings instituted by the other creditors. After stating the results of voting upon this question, Mr. Wright said that the first charge on the assets were the Six per Cent. Debentures, and the Five and a-Half per Cent. Debentures were a second floating charge. Doubts had arisen as to the rights of certain parties to vote; but the effect of inquiry on this point would be to increase, though not very substantially, the number desiring to institute proceedings. He had also to call attention to the letter of Mr. John Wood, holder of 6,000 Five and a-Half and 2,000 Six per Cent. Debentures, read at the meeting. It was dated October 29, 1895, and in it he wrote that it seemed to him that the question of proceedings against the Directors was one of a pure matter of business. He personally did not think very much would be recovered and no benefit would accrue except to the lawyers; but if there were people who thought otherwise, they would be prepared to pay a substantial sum to step into the position of the debenture holders, and if a proposal of that sort were made to him he would consider it on its merits. So that he did not abandon his claims.

His LORDSHIP: I am not bound to express an opinion, but I say I do not think the letter of that gentleman represents the commerce in the City of London generally. I think it is a private view of this gentleman.

Mr. MACNAGHTEN was about to address the Court for Mr. Wood and the other objecting debenture holders, when

His LORDSHIP said they must see whether this matter could be dealt with practically. Here were very serious charges against the Directors. Facts had been laid before counsel, who had advised that those parties would be liable on those facts to contribute large sums to the assets of the Company. Mr. Wood came forward and said: "I do not believe these claims are worth anything, but it is not my habit to do anything—even to assist justice—unless I am paid for it, and I expect to be paid for it. If I am paid for it I shall be pleased—more than pleased—to assist." Very well; what was Mr. Wood's figure? His Lordship continuing said: What I propose to do is to give Mr. Wood and his friends an opportunity of naming their price, and letting the unsecured creditors consider it.

Mr. MACNAGHTEN: Our position is perfectly intelligible. We do not think it is worth while bringing the action, but——

His LORDSHIP: Well, then, if it is not, it is not. But if your refusal to agree is only a commercial one, name your price—and I should say it ought not to be a big one. If these people do not want to sell because they wish to shield the guilty, I will not put them to the trouble of holding a meeting to consider their price.

Mr. AUSTEN CARTMELL, representing the Five and a-Half per Cent. Debenture-holders, pressed the Court to direct that proceedings should be taken.

His LORDSHIP said that the right thing to do was for the Receiver for the debenture holders to put their interest in these claims against the Directors and auditors up to auction and for the liquidator to buy, with directions as to the proper conditions.

For this purpose his Lordship again adjourned the summons.

New British Electric Installation Contractors' Company.

The examination of the Directors and officials of this Company (in bankruptcy) was resumed on Wednesday at the Shire Hall, Worcester, before Sir R. Harington.

Mr. TREE apologised for the absence of Mr. Duce on the last occasion, he having mistaken the date of the adjournment.

Mr. W. J. HILL (secretary to the Company) said that in drawing up any agreement between the old and new Companies he acted under the instructions of Mr. Millington.

His HONOUR said that the date of the signing of the debenture shares was very material, as Mr. Millington was not a shareholder of the new Company.

WITNESS said he was unable to give the date, but said they were issued in February, 1893; £130 was actually paid by Mr. Millington, and £125 by Mr. Griffiths, his partner, for shares; £425 was paid for Mr. Duce's shares held in trust by Mr. Millington, but no cash was paid for the 69 promoters' shares.

Mr. DUCE said he was not the only person connected with the Company who had an electrical knowledge; Mr. Millington was a very good commercial electrician. Witness had been engaged in the electrical trade in a general capacity. Before 1890 he had had little scientific knowledge. He was brought up in the spirit trade, at Wednesbury. He was adjudged a bankrupt at Walsall, and was still undischarged. He had had bitter experience in company matters. He could not say who suggested the formation of the New British Company. He thought the formation of the new Company was justified by the fact that the Corporation of Worcester had nearly finished their electric light station, and the Company had every reason to believe that there would be a large amount of additional work follow. The old Company wanted more capital to carry out some of the concessions, but as they did not get it they went on with the new Company on a better basis. He denied that the new Company was formed for the purpose of recouping losses which were sustained in the old Company.

Mr. JOHN MILLINGTON, recalled, said that the concessions would have become very valuable if money could have been found to work them. The old Company was not wound up with a view to getting rid of its liabilities. The bonuses were given for services rendered and money advanced, and he himself was given a bonus of £1,000, for which he had given months of service, both to the old and new Companies.

Mr. LUKE SHARP, the Official Receiver, asked if witness did not think £1,000 very considerable for services to a company that came to grief in 12 months.

WITNESS: How could it come to grief when it paid its debts?

Mr. Receiver SHARP: Yes, with the money of the new Company. If you had such confidence, why did you not issue shares instead of debentures?

WITNESS: My partner would go no further, and it was purely a matter of private arrangement. The Company fitted nearly the whole of the public buildings in Worcester for the electric light. No shareholder except the promoters themselves would lose a penny; those who had put money in would be indemnified by himself. Mr. Martin was the only shareholder who actually paid any cash for the debenture shares. He paid £500.

The examination was closed.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January 10, 1896.*

Storage Battery for Telephone and Telegraph Purposes.—The Western Union Telegraph Company and some of the district American Bell Telephone Companies have for some time been using small storage batteries for local service, and, it is said, with excellent results. The storage battery used is of the Planté type and of small size, costing about $1. As applied to telephony, the battery is under charge from the central exchange at all times when the receiver is on the hook, while when the receiver is removed for conversation the battery is switched into the local microphone circuit.

Gas Engines.—An electric railway plant is now being constructed in the West which will have an auxiliary gas engine for use during hours of heavy load, the object being to have the steam plant of such size that it may be worked near to its full capacity during the long hours of steady load. A gas engine has just been placed upon the market for use in isolated electric lighting, which is sold with the guarantee that the difference of speed will not exceed 1 per cent. for changes of load from 10 per cent. to full load. A company in Chicago has been installing gas-engine plants for block lighting, a recent plant supplying over 4,000 lamps in buildings on six blocks.

Telephony in Germany.—According to the report of the German Posts and Telegraphs Department, which has lately been issued for the year 1894, there were at the end of that year 475 German towns provided with telephone exchanges, as compared with 54 at the end of 1884. The number of inter-urban telephonic connections stands at 602, as against 22 ten years ago.

CORRESPONDENCE.

AN "ECCENTRIC" SYSTEM OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As to "An Eccentric System of Electric Supply," in your issue of 17th inst., I would like to have it explained how the common return differs in principle from both circuits being earthed at the far end and the corresponding dynamo terminals earthed also.

As far as practice is concerned it would be interesting to hear how the dual current affects the common return as to resistance, heating, &c. That is, suppose 1,000 amperes per square inch of conductor of continuous current is passed through, and also 1,000 amperes per square inch of alternating, is the volt loss that due to the sum of the currents, or do they not affect each other?—Yours, &c., J. E. RITTER.

Limavady, January 20, 1896.

[An unearthed common return connecting two systems differs from an earthed return in many respects, but chiefly in the fact that in the former case accidental interruption of the return circuit will send the current from one system into the other, whereas this cannot happen in an earthed return. The heat developed in a joint return conductor would, of course, be determined by the $\int c^2\,dt$ of the combined continuous and alternating currents, and would *not* be the sum of the heats developed separately by the two.—ED. *E.*]

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is in active preparation, and will be ready at the end of January. Orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. Full particulars post free on application.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

TENDERS INVITED.—The District Council of Swadlincote (Burton-on-Trent) invite tenders for the lighting by electricity of the thoroughfares of the township of Stanton. Particulars can be obtained from Mr. R. Cartwright, surveyor. Tenders must be in by the 27th inst.

——— The General Direction of the French Posts and Telegraphs requires tenders for the supply of 100 kilometres of submarine cable. Tenders to the Direction Générale des Postes et des Télégraphes, 103, Rue de Grenelle, Paris, by the 30th inst. The same department invite tenders for the supply of 500 tons (in five lots) of galvanised iron telegraph wire. Tenders by February 15th.

——— The municipal authorities of Soria, Spain, invite proposals for the concession for the electric lighting of the town for 20 years. Tenders to be sent to El Ayuntamiento de Soria by the 30th inst.

——— Tenders are invited for the concession for the electric lighting of Sainte Croix de Teneriffe, Canary Islands for 35 years. Tenders to the Ministère de la Gobernacion, Madrid, by Feb. 29th.

——— The Cologne Direction of the Prussian State Railways invites tenders for the supply of 137½ tons of galvanised iron telegraph wire, 5½ tons of bronze wire, 1½ tons of insulated wire, 12,300 porcelain insulators with supports, 17,400 porcelain insulators without supports, &c. Tenders to the Königliche Eisenbahn Direction, Domhof No. 28, Cologne.

TENDERS INVITED.—Tenders are invited for electric lighting work at the Zion Methodist New Connexion Chapel, Lindley, Huddersfield. Tenders to Messrs. John Kirk and Sons by the 29th inst.

——— Tenders are invited for certain electric bell-fitting work at the School for Technical Instruction, Maidenhead. Particulars from Mr. E. J. Shrewsbury, Queen-street-chambers, Maidenhead. Tenders by 4 p.m. on the 24th inst

——— Tenders are invited for installing the electric light at the Promenade Pier, Palace of Varieties and Marina Restaurant, by the Ramsgate Marina Pier and Lift Company. Particulars from the Secretary, 23, Martin's-lane, Cannon-street, E.C.

LIGHTING SCHEMES INVITED.—It will be seen by our advertisement columns that the Urban District Council of Eston, Middlesboro', invite schemes for lighting the district by electricity. A plan of the district can be seen and particulars obtained on application to Mr. F. W. Stainthorpe, A.M.I.C.E., District Surveyor, Grangetown, Yorkshire, to whom schemes must be sent in not later than May 1st next. Mr. Jno. T. Belk is clerk to the Council.

TENDERS ACCEPTED.—The tender of Messrs. Graham and Biddle has been accepted for fitting up an electrical-wiring installation with fittings in the new Chelsea Infirmary, for the Guardians, at £338. 12s. 6d.

——— The Bearpark Parish Council have accepted the tender of the Bearpark Coal and Coke Company to light the parish electrically. It is proposed to use 37 lamps of 32 c.p., and the charge is to be £3 per lamp per annum.

——— The British Thomson-Houston (Limited) and the Fowler-Waring Company have received orders from the Taunton Town Council for the supply of transformers and concentric cable respectively.

TENDERS RECEIVED.—The Shoreditch Vestry received ten tenders for the erection of the engine house and offices in connection with the Vestry electric lighting scheme. The tenders, which varied in amount from £10,540. 16s. to £8,535, have been referred to a Committee for consideration and report.

POSTPONEMENT OF SALE.—The sale by auction by Messrs. Wheatley Kirk, Price and Goulty of the works at Acton Hill, referred to in our last issue, has been postponed from the 29th inst. to a future date, particulars of which will shortly be announced.

APPOINTMENTS VACANT.—The Corporation of the Borough of Plymouth invite applications from duly qualified persons for the important office of Electrical Engineer to the Corporation. It will be seen by the advertisement on another page of the present issue that applicants must have had previous experience in a similar capacity to a corporation or a company supplying electric current under Parliamentary powers, and must be competent to design and superintend the construction of generating plant, &c. Commencing salary £300 per annum, rising to £400. Applications have to be sent in to J. H. Ellis, Town Clerk, Municipal Buildings, Plymouth, not later than February 14th.

——— A general foreman for an electrical engineering works is required. Regarding the appointment some particulars are given in our advertisement columns.

REMOVAL.—The City office of the Southgate Engineering Company (Limited), makers of electric, steam and hand cranes, and whose works and chief offices are at New Southgate, N., has been removed from 172, Fenchurch-street, to Leadenhall House, Leadenhall-street. This office is under the management of Mr. James Reid.

DISSOLUTION OF PARTNERSHIP.—We are informed that the partnership lately existing between Messrs. E. W. Donovan and F. C. Twemlow, trading as J. S. Leach and Co., mechanical and electrical engineers, &c., at Harpurhey and at Broughton Bridge, Salford, has been dissolved. The business is carried on as formerly under the same name by Mr. E. W. Donovan, who pays and receives all debts due by and to the late firm. The dissolution dates from November 30th last.

LIQUIDATION.—A meeting is to be held at 38, Coleman-street, E.C., on February 17th, at 11 a.m., for the purpose of receiving an account of the winding-up of the International Electric Subway Company (Limited).

THE GÜLCHER COMPANY.—In the action brought by the Liquidator of the Gülcher (New) Electric Light and Power Company against a Mr. Murray the defendant was successful in proving his non-liability for the payment of the sum of £300. Mr. Justice Vaughan Williams decided that Mr. Murray only accepted the allotment of certain debentures on certain conditions, which were not fulfilled; but the point in the action which has the greatest interest for ourselves, and will doubtless interest many of our readers, is the statement made by Mr. Gore Brown, who represented the plaintiffs, "that the assets of the Company would prove

Digitized by Google

ample for the payment of the costs in the action, and as this was the last incident in the winding-up of the Company the time would be very short before the costs were paid." Perhaps some of the creditors and contributories of the Company can also share in the distribution of these assets, although in a letter before us the Liquidator writes to a correspondent: "I regret to inform you that there is no prospect of a dividend being paid" in this matter. At a meeting of shareholders and others called some time back the Chairman gave those present to understand that on the realisation of the New Zealand Company's assets funds would doubtless be forthcoming to liquidate all liabilities.

PERSONAL.—We are asked to state that Mr. L. Pyke (late of Messrs. Pyke, Harris and Co., Limited, Westminster) has sent in his resignation to that Company as Managing Director, owing to his having entered into partnership with Mr. Owen Lucas and Mr. Leopold Lucas under the title of Messrs. Owen Lucas and Pyke, consulting engineers.

PORTABLE LIGHTS.—The arrangement adopted by the London General Omnibus Company to provide its ticket inspectors with pocket batteries and button-hole electric lamps has been followed by a similar equipment of the ticket inspectors at the Vauxhall Station of the London and South-Western Railway. All up-train tickets over the South-Western Company's extensive lines are collected at Vauxhall. The arrangement is on trial, and if successful should lead to a large demand for these serviceable lamps and batteries. It has been suggested that the postal department might substitute electric lamps for the cumbersome bullseyes now used by suburban and provincial postmen.

GEIPEL'S STEAM TRAP.—We have received a copy of a new price list for this contrivance, issued by the Shillingford Works Company. The list states that during the past year the trade in these traps has rapidly increased. A description of the trap appeared in *The Electrician* for November 23, 1894. Many electricity supply stations are using the traps.

ELECTRIC SIGN.—A new form of electric sign has been brought out by the Jewels Advertising Syndicate, of New Oxford-street. It consists of a glass cylinder, composed of strips of coloured glass, which revolves slowly between a row of glow lamps fixed to a rod suspended inside the cylinder between its bearings and the sign or line of letters intended to catch the public eye.

TRUNK TELEPHONES.—The Post Office trunk telephone lines are to be extended to Portsmouth, which town will, it is stated, be in direct communication with London at the end of this month.

POCKET CATALOGUE.—While some leading firms in the electrical industries find it necessary to issue from time to time large volumes of illustrations, prices and particulars of their manufactures, other companies are in the fortunate position of being outside the necessity for this heavy expenditure. We have received from the Electrical Power Storage Company (Limited), of 4, Great Winchester-street, E.C., a handy pocket-book, which gives all necessary particulars concerning the well-known E.P.S. batteries. The Company's terms for maintenance, instructions for working E.P.S. batteries (with plan of general arrangement), illustrations, prices and particulars of various types of cell, charges for renewals and particulars of sundry apparatus used in connection with the batteries, are duly set out in a neat pocket companion 5in. by 3½in. The letterpress is printed from photo blocks, which somewhat mars its clearness. The offside of the printed matter is scale paper, and several useful fuse, resistance, acids, &c., tables are included.

MEDICAL SURGICAL APPARATUS.—Mr. K. Schall sends a copy of his new price list of apparatus for utilising currents from dynamos for medical and surgical purposes. The list is illustrated.

CALENDAR.—Messrs. Shand, Mason and Co., the well-known fire engineers and experts, of Upper Ground-street, Blackfriars, London, send a pictorial calendar neatly designed and arranged, from which, amongst other matter, we find that 36 powerful engines of Messrs. Shand and Mason's make have been supplied to the London County Council. The same firm also issue an "occasional" circular, which those interested in fire brigade department matters should obtain.

BAKER-STREET AND WATERLOO RAILWAY.—The engineers of this railway have deposited with the Private Bill authorities an estimate of the cost of the proposed extension of the railway to the St. John's-wood terminus of the Sheffield Extension Railway. The cost of the additional length of line is put at £99,043.

BRADFORD.—At a meeting of the Gas Committee of the Bradford Corporation on Friday last it was decided to have a survey made of the land at Valley-road required for the purpose of the proposed extension of the electricity works.

BRIGHTON.—At the meeting of the Town Council last week, the report of the Electric Lighting Committee, referred to in our last issue, was, after a short discussion, agreed to.

CARDIFF.—The Lighting Committee have just prepared their estimates for the next half year, and it is anticipated that there will be a profit of £848 on the electric lighting department, a sum sufficient to meet interest, expenses, &c., and the repayment of the loan.

CAMBERWELL (LONDON).—At the meeting of the Vestry last week the special Electric Lighting Committee reported that they had considered the notice received from the County of London and Brush Provincial Company for a Provisional Order. The Committee recommended that the Board of Trade be informed that the Vestry would offer no objection to the application provided that separate accounts be kept for Camberwell, and that after the expiry of 21 years the Vestry may have the option to purchase the undertaking. The Committee's report was, after some discussion, adopted.

COLCHESTER.—A special meeting of the Town Council was held last week for the purpose of further discussing the special report recently presented by the Lighting Committee on the question of establishing electric light works in Colchester. An abstract of this report appeared in our issue of the 3rd inst., and the Committee now further recommended the Council to purchase the piece of land adjoining the Stanwell-street depot for £500, to serve as a site for a station. It was stated that the War Office authorities offered to take current for about 500 lamps at the new Military Hospital, provided the charge did not exceed 6d. per unit, and that the supply was available by May next. The Committee recommended the Council to accept this offer, and that a communication be made to the Department, asking that, in the event of the electricity works being established, the Council be also allowed to supply current to the new Infantry Barracks, where about 750 lamps would probably be required. As to the estimated cost of the work the Committee reported that they had been in communication with Mr. W. H. Massey with a view to ascertaining the lowest possible expenditure which a scheme for lighting North Hill, Head-street, High-street (from North Hill to the end of St. Nicholas-street), St. Botolph's-street, Long Wyre-street, Short Wyre-street, St. John's-street, and part of Stanwell-street, and also the barracks and Military Hospital, would involve, and Mr. Massey put this initial outlay at £13,000. Mr. Barritt moved the adoption of the old report, but Mr. Nash moved an amendment that they invite schemes, with plans and specifications, from four firms of good standing, and arrange terms with Mr. Massey to advise them on such plans. The report was after some discussion adopted in the amended form. The new report was then put, and carried by 14 votes to 2.

COVENTRY ELECTRIC TRAMWAYS.—On Thursday last the section of this line, from the tramway depot at Foleshill to Bedworth, was officially inspected on behalf of the Board of Trade, and it is expected that the entire line will in a few days be certified for working.

DERBY AND ASHBOURNE ELECTRIC TRAMWAY.—A detailed estimate of the cost of the proposed electric tramway between Derby and Ashbourne has been prepared by Messrs. A. Dickinson and Co., of Birmingham. The length of the tramways will be nearly 12 miles, but only one mile will be constructed as a double line, and it is estimated that the entire work will involve an expenditure of £31,172.

EDINBURGH.—At the last meeting of the Council, a letter was received from Mr. E. W. Monkhouse, intimating that he had determined to start in business in London as a consulting engineer, and therefore tendered his resignation as borough electrical engineer. The Lord Provost said they were all very sorry to lose Mr. Monkhouse, who had done his work with great energy and success. It was agreed to accept the resignation with regret, and to remit the question of the appointment of a successor to the Electric Lighting Committee. The Town Council at their meeting on Tuesday discussed the joint report of the Cleaning and Lighting and the Electric Lighting Committees referred to in our last issue. The report recommended the Council to carry out various extensions of the public electric lighting. Councillor Mackenzie, in moving its adoption, said ample provision had been made for the lighting of all the main streets of the city, and if the Council adopted the present report they might consider this question of extensions pretty well finished, at any rate for the present. He estimated the total capital expenditure for the present extensions, which would necessitate the erection of 237 lamps, at £11,850. He was certain that if the Council continued to take the same broad view of the electric lighting question which it had hitherto adopted, in 12 months' time it would be possible to reduce the charge for street lighting to £16 per lamp per annum. Mr. Jamieson moved the recommittal of the report, and Bailie Anderson seconded the amendment and said that, though he admitted that great improvement was necessary in the street lighting, still he thought "they were going wild on the matter of electricity," and he thought such expenditure injudicious, in view of the very large and important scheme already in hand. After considerable discussion, the proposals of the Committee were taken *seriatim*. The first, which provided for 36 lamps at an annual cost of £648 for the lighting of Morningside was defeated by a small majority, while another proposal for the extension of the mains into Stockbridge was reduced by 10 lamps, thus diminishing

Digitized by Google

the cost of the whole scheme by about £800. The remainder of the Committee's proposed extensions were adopted.——It is proposed to light City Chambers and Royal Exchange-square electrically at an estimated cost of £256.

ELECTRIC RAILWAY EXTENSIONS.—In connection with the extension of the City and South London Railway to the Royal Exchange, a meeting was held at the Mansion House on Wednesday to recommend that opposition be offered to the proposal to demolish the church of St. Mary Woolnoth, at the corner of Lombard and King William-streets. This was the church where some years ago it was discovered that owing to various causes the bodies buried beneath the structure emitted insanitary odours, and a suggestion was then made that, for the general benefit it would be advisable to seriously consider the demolition of the church. It appears now, however, that the attempt of the City and South London Railway Company to obtain the position for the purpose of erecting station in connection with the proposed extension is to be desperately fought. One of the grounds upon which this action is proposed to be taken is that the church was built by a pupil of a pupil of Sir Christopher Wren, a further reason being that one of our leading banking firms has for 600 years carried on its business under the shadow of of St. Mary Woolnoth. There are dozens of city churches in the immediate neighbourhood, in a very few of which do the citizens foregather either on Sunday or week-day, and the opposition to the proposals of the Company seem purely sentimental. There is no objection to be taken to this if the sentiment is healthy and has reason for its foundation, but in this case the building to be demolished has nothing to recommend it from an architectural point of view, and its position is not a favourable one for a church, whereas for a passenger station, which would materially assist to reduce the excessive and dangerous pedestrian traffic at this point, the position is a most desirable one. There was a lack of real feeling in the matter at the meeting, and it is doubtful whether success will attend the proposed opposition.

EXETER.—On the 16th inst. Col. J. O. Hasted, R.E., held a Local Government Board inquiry into the application of the Council to borrow £11,000 for the purchase of the undertaking of the Exeter Electric Light Company, and for the construction of works, in the event of the Council being empowered to purchase the undertaking. The Town Clerk (Mr. G. R. Shorto) supported the application, while Mr. Pitt Lewis, Q.C., appeared on behalf of opposing ratepayers, and the Exeter Company were represented by Messrs. C. T. K. Roberts and S. Andrews. Dr. J. A. Fleming was the first witness called, and said he had made a complete inspection of the whole of the Company's plant and buildings, and he considered that it would be advisable for the Corporation to purchase the undertaking, as in all cases in which local authorities had the electric light under their control a profit had been made. He valued the undertaking at £7,500. New and independent electricity works could not be erected for less than £10,000. The City Surveyor (Mr. Donald Cameron) said he valued the undertaking at £7,556. The building he estimated at £1,000, plant at £3,200, and mains, motors and transformers at £3,156. Mr. H. D. Munro, chief engineer of the Exeter Company, put the value of the concern at £12,000. Mr. A. E. Mavor, manager of the Fowler-Waring Cable Company, was also called, and he stated that the cables were originally laid under his supervision. They were of the highest quality known at the time, and there was now no trace of deterioration. The Secretary of the Local Company (Mr. E. J. Rigby) gave details of the working of the Company. The inquiry was then adjourned till Saturday, when further evidence was given in support of the application. Mr. Pitt Lewis, Q.C., intimated that he would call no witnesses, but he maintained that the value of the undertaking was not anything near the figure given in Dr. Fleming's evidence, and that the present financial condition of the Corporation did not warrant them in purchasing the works. Mr. Roberts replied on behalf of the Company, and the proceedings then terminated.

FAREHAM.—Application was made on Wednesday for a stay of execution for 14 days in the award recently made by the Court against the District Council for £3,800 damages in the action brought by the Fareham Electric Light Company, the contending parties not having arrived at a satisfactory arrangement.

GLASGOW.—At the meeting of the City Council last week a long discussion arose on the Electric Light Committee's report. Mr. Guthrie referred to the small increase in the income from the sale of electric current, viz., £167 10s., and he thought the recently-appointed sub-committee should visit other towns where the electric light had been adopted. Treasurer Gray and Mr. Fife defended the action of the Committee, and Mr. Walter Paton admitted that the electric light had not been such a success as it ought to have been in a city like Glasgow. Mr. W. F. Anderson said the committee had hitherto been going on too narrow lines, and the undertaking would never prove a success until it was entirely dissociated from the Gas Committee. He considered that, after what Glasgow had done in other respects, they should not be dependent on the example of Edinburgh. Mr. Bailie Burt, the convener of the Committee, in his reply, deprecated the statements made as to their non-success. He had no hesitation in asserting that the electric light in Glasgow had been an unqualified success. Various extensions had, from time to time, been made, and even now the Committee had a proposal before them for further extending the system. It was true that they had lost one of their best customers, the Post Office, who had laid down an independent plant, but in spite of this fact their revenue continued to increase.

HANLEY.—At last week's meeting of the Town Council the General Purposes Committee presented the report by the borough engineer and surveyor, Mr. Joseph Lobley, and signed by the joint managers of the electric lighting works. The year's working of the electricity works shows most gratifying results. The report repeats the notification that although the covered market and fish market are wired completely for the electric light, and have been so wired since the autumn of 1894, the demand for current for other purposes so closely exhausts the available power at the station that it has not been considered safe to light the markets by electricity. Owing to the sanction of the Local Government Board for the extension asked for in March, 1895, not having been received till November last, the new plant has not been available for supply during the heavy load of the last few months. Notwithstanding these drawbacks there are now 11,550 lamps connected. The report refers in some detail to the question of the reduction of the price of current, and to the fact that a reduction equal to 16 per cent. (from 6d. to 5d.) has naturally been considered by those responsible for the preparation of the report as a serious matter, and that, therefore, it was determined to await the result of the first year's working under constant supply conditions before advising on the subject. The announcement is then made that sufficient details are to hand to show that the revenue has exceeded expenditure by more than £100, after allowing for interest and repayment of loans. On the whole, however, it is Mr. Lobley's opinion, in which he is supported by Messrs. Cowell and Sutherland, the joint managers of the works, that the time has not come for a reduction in the price per unit being made, except in the application of the Brighton system, regarding which more than usually complete particulars are given for the benefit of the councillors. It is proposed that the existing price of 6d. per unit shall be the basis of the arrangement as now, but that the 5 per cent. discount hitherto allowed should be discontinued. It is also proposed to practically abolish meter rents and to introduce certain abatements for prompt monthly payments on accounts of £1 and upwards. Alderman Shirley, in submitting the report, pointed out that it was hardly anticipated when the electric light undertaking was first discussed that there would be any reasonable prospect of profit at least for some years. This, however, thanks to the able officials who were responsible for the working of the concern, had not proved to be the case, but after meeting all charges, there was already a moderate balance to put to reserve. He proposed the adoption of the report, and with special reference to the rearrangement of charges, including the charge of 4d. per unit for churches, chapels, &c., requiring light principally on Sunday evenings. This was seconded and unanimously adopted. Certainly all concerned are to be congratulated upon the results attained. Of the amounts borrowed from time to time for electric lighting purposes, £13,747 remains available for future extensions. The actual working expenses of the station were £2,286, and the revenue £3,724. 3s. 8d. £754. 8s. 10d. has been paid for interest, and £587. 18s. 10d. has been set aside for repayment of loan. 180,000 units of current were sold during the year.

HUDDERSFIELD.—The London and Provincial Traction Company (Limited) has deposited a Bill in Parliament for power to incorporate the Halifax and District Tramway Company and to construct tramways in and near Halifax. The Company recently approached the Huddersfield Corporation with a view to obtaining a lease of the Council's tramways for the purpose of connecting the system with the Colne Valley, Brighouse, Elland and Halifax. The chairman of the Company, in reply to an inquiry from the Corporation, has sent a lengthy letter to the latter body, in which he points out the advantages of having Huddersfield connected with the various towns above-mentioned by a system of electric tramways. He was unable to say at present what expense would be involved in the construction of the suggested line, but it was the intention of his Company to lay a large extent of double lines in order to increase the frequency of the car service. The Corporation have appointed a sub-committee to consider and report upon the matter.——The electrical engineer has been instructed to prepare an estimate of the cost of the proposed lighting of the top portion of the Market Hall, and a sub-committee has been appointed to consider and deal with the report when presented. It has also been decided that, in the event of the re-pavement of King-street, the engineer is to have electric lighting mains laid in the street.

JERSEY.—It is reported that the Parochial Assembly is disposed to accept the proposal made by a French Company to supply the town of St. Heliers with electric current. An offer has also been made, we understand, by the Jersey Gas Light Company to supply whatever electric current is necessary for the town.

Digitized by Google

LIVERPOOL.—At the annual meeting of the Liverpool United Tramways and Omnibus Company, the Chairman (Sir David Radcliffe), in moving the adoption of the report and accounts, referred to the efforts the Directors had made to introduce a suitable system of mechanical traction on their lines. First of all steam was tried, but the Corporation were opposed to its use, and then experiments were made with compressed air and the accumulator system of electric traction. The latter system proved suitable in every respect except as to cost, which they found would be more than 15 per cent. above the cost of horse traction. Finally, the Company had turned their attention to the cable system, but this proved to be the least suitable of all for their lines.

MAIDSTONE.—The Electric Lighting Committee recommend the Council to transfer their Provisional Electric Lighting Order to Company, to be promoted by Mr. Thomas King, electrical engineer, of Brighton and Maidstone.

MERTHYR TYDVIL.—At the last meeting of the District Council the Parliamentary Committee reported that they had seen Mr. J. C. Howell in reference to his application for a Provisional Order for lighting the district electrically, and he had met them to the extent of increasing the area proposed to be lighted electrically. The question of the purchase of the undertaking was also discussed, and it was stated that on certain conditions the Council would be prepared to give their consent to the Order.

MILE END (LONDON).—The consulting electrical engineer of the Mile End Guardians (Mr. B. H. Jenkinson) has submitted plans, &c., for the proposed electric lighting of the workhouse, and these have been referred to the Works Committee, who have been instructed to consider and report on the same.

OKEHAMPTON.—Recently the Charity Trustees decided to have the town clock lighted electrically, and the work has just been completed by Henry Green, of Okehampton.

PERTH.—At the last meeting of the Police Commission Mr. Wood moved that it be remitted to a sub-committee to consider and report as to how the spare power under the control of the Corporation could be best utilised with a view to the electric lighting of all the Corporation buildings. The motion was agreed to.

PERTH (W. AUSTRALIA).—The *Newcastle Journal* states that Messrs. J. H. Holmes and Co., of Newcastle, have entered into a contract to re-organise the electric lighting arrangements at Perth. The work will involve the establishment and full equipment of a central station of as large a capacity as that which the firm are now fitting up at Sunderland, and on the same lines.

SOUTHAMPTON.—A meeting of the Harbour Board is to be held on Tuesday next for the purpose of considering an offer from the Southampton Electric Light Company to supply current at a reduced rate.

ST. JAMES'S (LONDON).—At the last meeting of the Vestry the Works Committee recommended that the following thoroughfares be lighted electrically, viz.: Regent-street, Piccadilly-circus, Shaftesbury-avenue, Coventry-street, Lower Regent-street, Waterloo-place, Pall-mall, St. James's-street and Piccadilly, and that it be referred to a committee to take the necessary steps for carrying out the work in connection therewith. Mr. W. Jenkins, in moving the adoption of the report, said the St. James' and Pall Mall Company would maintain and keep in repair each lamp for £30 per annum. The lamps would be erected in the centre of the street on iron posts 25ft. high, and each would form a refuge. The lamps would be of the same candle-power as those in the Tottenham Court-road and Euston-road, and if the Committee's recommendation were adopted the light in the streets named would be increased about 800 per cent. The lamps are to be placed 60 yards apart, and will be distributed as follows: 16 in Regent-street, 6 in Piccadilly-circus, 4 in Shaftesbury-avenue, 2 in Coventry-street, 5 in Lower Regent-street, 3 in Waterloo-place, 8 in Pall Mall, 8 in St. James's-street and 8 in Piccadilly.

SWANSEA.—On Wednesday last Col. W. M. Ducat, R.E., held a Local Government Board inquiry into the application of the Council to borrow £60,000 for the purpose of erecting electric lighting and dust destructor works. The Corporation were represented by Mr. S. T. Evans, M.P., while Mr. Villiers Meager appeared for the Swansea Coffee Public House Company, who opposed the dust destructor portion of the scheme. Evidence in support of the application was given by the Mayor (Alderman Fred. Bradford) and the Town Clerk (Mr. J. Thomas). Mr. Meager said the ground of his client's opposition to the dust destructor was that it would be offensive to the Company's customers at the Welcome Tavern. Several gentlemen then endeavoured to offer opposition to the Corporation's tramway scheme, but the Commissioner pointed out that he had only to deal with the electric lighting and dust destructor proposals. Mr. Thornton Andrews (Manager of the Gas Company) also opposed the application, and gave certain figures, which he contended proved that gas was cheaper than the electric light. The ground for the opposition of the Gas Company was that the Corporation desired to secure the public and private lighting of the central part of the town, leaving the Gas Company to light the outside districts, where the private consumption of gas was at present almost *nil*. In cross-examination Mr. Andrews admitted that the Company had themselves considered the question of forming an electric lighting company, but that was, of course, owing to the action of the Corporation. The inquiry then closed.——The estimate of the cost of constructing the 28 sections of the new tramways set out in the Corporation Tramways Bill has been prepared by Mr. J. E. Waller, C.E., and is put at £31,315. 17s.

WIMBLEDON.—As a result of the recent Local Government Board inquiry and the notification received by the Council from the Board, it has now been decided to apply for a Provisional Order in place of the licence expiring in July next.

WORKHOUSE LIGHTING.—The House Committee of the Sunderland Board of Guardians have appointed a sub-committee to act in conjunction with the architect of the new workhouse buildings to ascertain (1) the cost of putting down an independent plant for generating electric current for the lighting of the workhouse, and (2) the lowest figure at which the Corporation would supply current from their station.

WORCESTER.—A Sub-Committee of the Watch Committee are considering the advisability of extending the public electric lighting.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

January 6, 1896.

342. J. R. WELLAND. London. A new or improved combined portable electric light and current generating apparatus.
347. C. B. WOOD. London. An improved switch for electrical purposes.
355. A. L. DAVIS. London. An electrical regulator for regulating arc lamps and for other purposes.

January 7, 1896.

390. J. T. LEROUX. Birmingham. Improvements in electrical switches.
452. H. H. LAKE. London. Improvements in apparatus for controlling electric motors. (Bradley, Allan Fiske, United States.)*
474. W. C. BERSEY. London. An improved turning plate for electrically or mechanically-propelled vehicles.
475. W. C. BERSEY. London. Improvements in electric accumulators.
477. C. N. STEWART. London. Improvements in electrical storage accumulators.

January 8, 1896.

533. SIEMENS BROS. AND CO (LIMITED). London. Improved automatic remontoir apparatus for Hughes's telegraph apparatus. (Siemens and Halske, Germany.)
535. H. W. HEADLAND. London. Improvements in primary and secondary batteries.
546. R. J. BOTT. London. Improvements relating to electric incandescent lamps, and to adapter fittings therefor.
547. H. EDMUNDS. Improvements in devices for joining or connecting electrical cables or conductors.
551. L. B. ATKINSON. London. Improvements in dynamo-electric machines and motors.
557. R. COLLINS and F. COGAN. London. Improvements in electric batteries
565. H. H. LAKE. London. Improvements in apparatus for transforming continuous electric currents. (Cie. de l'Industrie Electrique, Switzerland.)

January 9, 1896.

604. S. W. BAYNES. London. Improvements in insulated anchoring apparatus for use on underground or overhead conductors of electricity.

January 10, 1896.

699. H. N. MOODY. London. Improvements in electric arc lamps.
701. B. MARINOVITCH. London. Improvements in electric signalling apparatus.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1895.

20,435. DEVONSHIRE (Case). Electric brakes.
20,940. JOHNSON (Woodbridge). Printing telegraphs.
21,556. THOMPSON (Hammacher and Paetzold). Telephone transmitters.
21,623. FOX. Electric lamp fittings.

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The forty-seventh half-yearly meeting of this Company was held on Thursday, at Winchester House, the Marquis of Tweeddale (Vice-chairman) presiding.

The SECRETARY (Mr. George Draper) read the notice calling the meeting.

The CHAIRMAN expressed regret that the respected Chairman of the Company, Sir John Pender, M.P., was confined to his house; but he hoped that the indisposition from which he was suffering would pass away speedily. He believed that a little rest from his arduous labours, and, perhaps, a visit to a more genial climate, would restore Sir John to his usual good health. The half-year which was under notice was the most satisfactory that the Company had ever experienced. It was distinguished by two very satisfactory features. One was a large increase in the receipts, and the other was a decrease in the expenditure. The gross revenue for the half-year amounted to £409,780, against £362,557 in the corresponding period of 1894, an increase of £47,223. An examination of the message receipts from various sources showed a satisfactory increase in all classes of traffic. The principal increase was in the traffic with West Australia and South Africa, which was due to the activity that had taken place in the gold-mining markets. With regard to the traffic with South Africa it was satisfactory to note that, notwithstanding the large reduction in the tariff, an increase had taken place in the value of the traffic at the former rate, but as this was entirely due to special circumstances they could hardly count on its being maintained. The total ordinary expenses for the six months ending September 30th last amounted to £96,704, against, in the corresponding period of 1894, £97,533, or a decrease of £829. Although every care was taken in controlling the expenses, the shareholders must not be surprised if in the future the amount became larger. Their business was growing so rapidly that an increase in the expenditure must be contemplated by them. After providing the usual amount for interest on debentures and debenture stock and the usual two quarterly dividends, they were enabled to carry £10,000 to the maintenance of ships' reserve, £50,000 to the general reserve fund, and the balance of £49,352 it was proposed to carry forward to the next half-year. The value of their reserve fund, about £422,000, showed an appreciation of nearly £60,000, so that altogether the accounts might be fairly considered as very satisfactory. He was glad to say that their cables were, speaking generally, in a very good condition. These cables were, however, of all ages and all lengths, and in seas differing very much in condition in respect of cable-laying. In view of these facts and of the numerous interruptions that occurred the necessity was apparent of further increasing their reserve fund, which, in the opinion of all those whose opinion was worth having, was in a very inadequate state at the present time. The sum at which it stood was about £422,000, but it should be something like double that before it could be regarded as satisfactory. It might interest them to know the actual facts with reference to their recent interruption on the east and west coast of Africa. On December 24th the Aden-Zanzibar cable was interrupted. They had two ships available for its repair, one belonging to the Eastern Extension Company, which had just left Suez and was on its way to Aden, and the other to the Eastern and South African Company, stationed at Cape Town. The latter Company found by hiring the Eastern Company's ship there would be a saving of about a week in restoring the cable, and orders were given for that vessel to proceed to the spot. She hooked the Aden end of the cable at the second swoop, and communication was restored on the East Coast on January 4th. Meanwhile events had happened in the Transvaal the nature of which they were aware of, and the West Coast route had been called on to perform an enormous amount of additional traffic. Until December 30th the West Coast route was able to keep up to the traffic, but on the news of Dr. Jameson having crossed the frontier of the South African Republic the line became occupied almost entirely by telegrams sent by and to European Governments, who had the right of priority of transmission, and this particular traffic was transmitted without exceptional delay. Immediately the East Coast route was restored the delay began to diminish, and on January 10th they had recovered their normal condition of working. It was a time of great anxiety to the Board. They desired to do everything to meet the demands made on them, and he believed they succeeded. At any rate not a single complaint, as far as he was aware, had come from our own Government. On the contrary, he had reason to think that our own Government were highly satisfied at the manner in which the business was done, and they had not received any complaint from any other Government having large interests with South Africa. He thought they might look forward to the coming half-year with confidence. The war clouds were lifting, and the traffics continued good, reflecting, he believed, the improved condition of business and commerce. With these observations he moved the adoption of the report and accounts.

Lord SACKVILLE A. CECIL seconded the motion.

Mr. BAINES, after alluding to the regret he believed all the shareholders felt at the illness of Sir John Pender, complained that, notwithstanding the splendid traffic of the half-year under review, the ordinary shareholders were left with the same dividend as before. He thought the ordinary shareholders were entitled to more liberal treatment at the hands of the Board.

Capt. GOODSALL also contended that the ordinary shareholders should be paid a larger dividend.

Mr. JOHN NEWTON said he did not agree with Mr. Baines and Capt. Goodsall that the dividend was a small one. It was a large one in his opinion, and he thought that, having regard to the remarkable career and success of the Company, the shareholders might be content to leave the management of its business and finance to the Directors. He also expressed regret at the indisposition of Sir John Pender, and hoped the Chairman would convey to him the sympathy of the meeting (hear, hear).

The CHAIRMAN, in reply, said he should take an early opportunity of conveying to Sir John Pender the kind expressions which had fallen from several shareholders, and which, so far as he could judge, had been cordially received by the whole meeting. (Cheers.) He would remind Mr. Baines that that was the half-yearly meeting, and it was not usual to expect so large a dividend on such an occasion as at the close of the financial year. The remarks and suggestions which had fallen from him and other shareholders would, however, have the careful consideration of the Board.

The motion was then adopted.

The CHAIRMAN then proposed the re-election as a Director of Lord Sackville A. Cecil.

Sir ALBERT J. LEPPOC CAPPEL seconded, and it was agreed to.

The CHAIRMAN next proposed the re-election of Mr. G. G. Nicol as a Director, who, he stated, was also absent through illness.

Lord SACKVILLE A. CECIL seconded, and it was carried.

On the motion of Mr. BAINES the auditors were reappointed, and the proceedings terminated with a vote of thanks to the Chairman, proposed by Mr. J. NEWTON.

[A full report of this meeting will appear in our next issue.]

Direct United States Cable Company (Limited).

The thirty-seventh ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Tuesday. Sir John Pender, G.C.M.G., M.P., presided.

The SECRETARY (Mr. T. Finnis) read the notice convening the meeting and the minutes of the last ordinary general meeting, which were confirmed. The report of the Directors was taken as read.

The CHAIRMAN: The revenue for the six months to December 31st (forming the first half of our current financial year) amounted in round figures, and after deducting the out-payments, to £43,938, and the working and other expenses, including income-tax, but exclusive of cost of cable repairs, absorbed £19,058, leaving a balance of £24,880 as the net profit of the half-year, making, with £1,410 brought forward from the previous half-year, a total of £26,290, which has been appropriated as follows:—Interim dividend of 2s. per share for quarter to September 30th last, £6,071; further interim dividend of 2s. per share for quarter to 31st December last, £6,071; set aside to reserve fund account, £10,000; leaving a balance to carry forward to the current half-year of £4,148. The revenue, which had commenced to improve in the early part of last year, has still further progressed during the past six months, for which period it shows an increase of £5,596, or more than 14 per cent. as compared with the corresponding six months of 1894. The expenses in London, as shown by abstract A in the accounts, are a little higher in one or two cases, but most of the items remain practically the same as in the corresponding period of 1894. The expenses at stations, as shown by abstract B in the accounts, exhibit reductions of £124 in salaries, £15 in petty expenses, £121 in printing and stationery, and £138 in agencies, with an increase of £104 in maintenance. Altogether these disbursements show a reduction of £216. In the remaining expenditure a saving of £158 is shown in Directors' remuneration, while use of patents cost £150 more, due to the automatic transmitter. This automatic transmitter, I may mention, is an invention whereby we increase the speed of our cables by about 30 per cent. Freight of cable stands for £214 extra through the sending out to our tanks at Halifax of stock cable for repairing purposes. The aggregate ordinary expenditure of the Company is only £34 greater than the corresponding period, notwithstanding the before-mentioned considerable increase of 14 per cent. in the receipts. The cost of cable repairs has, unfortunately, been heavier than for a considerable period, having amounted to £6,984, which has been charged against the reserve fund account, as usual. On the other hand this fund has been credited with £4,619 for interest on the investments and with £10,000 from the revenue account, bringing the balance of the reserve fund up to £306,005. It was higher at one time—nearly twelve years ago—but since that time we have had very heavy repairs made, one of which cost us £58,814. The investments have been increased during the half-year by £16,400 and the present market value of the investments as a whole is about £335,000, or about £50,000 more than their cost to the Company. We have considered it very advisable to keep up our reserve fund. We are getting to a period when our cable will have reached 25 years of age, and although we have put in a great many repairs during the last twelve months—in fact, in the last two or three years—still, we find that if we were to be suddenly brought to our beam ends, we should be short of the amount required to give us a new cable. We have, therefore, always to look ahead and take care that we are not caught sleeping. The six months which we have passed through has been rather an exciting period. We have had a great many things going on in America which have naturally caused us some anxiety, but I still think that common sense will prevail, and that it will bring about a settlement of the question which is being agitated in America now. There may probably be some reason for this agitation at the present time, seeing that an election in the United States is not far off, and people there generally get up some excitement on such an occasion to carry their party into power with its followers. I do not expect it will come to much, but at the same time when people get into a little excitement it is not very easy to judge what they may do. Nevertheless I think that there is common

Digitized by Google

sense sufficient to prevent anything like a war between America and England—people of the same blood, who, I believe, may eventually dominate the world. We have received four letters from different shareholders, all complaining, and very properly complaining of the want of dividend. We have passed through very hard times, probably the hardest ever seen in the United States, but we are very much improving, and I am hopeful that when things settle down in America we shall go improving still further. Meantime I wish to be courteous to the gentlemen who have written to us to say that they hope we shall give them more dividend. We should be only too glad to give them more, but we have to be careful not to give away that which we may require. Mr. Houston, of Dumfries, writes asking for a higher dividend, and he is entitled to consideration. He holds 120 shares. Mr. Maxwell, also of Dumfries, writes a very sensible letter, with which I have no fault to find. Mr. John Woodman, of Exeter, and Mr. Steel, of Newcastle-on-Tyne, also ask us to give the shareholders an additional dividend. We have only had these four letters, and I am not very much astonished that these gentlemen have written. We have shown a very considerable increase this half-year. The current six months is the final period of our financial year, and I hope that if things go on as well as they are now, I shall be able to give you something in the shape of a better dividend. I daresay you think I am exceedingly cautious, but I find that it is far more easy to declare a dividend than it is to get one back. Therefore, we have to look round and see that all our system is in proper working order, and we must see six months ahead of us, but with that period ahead of us I think I can promise you something more than we are giving you to-day. I may repeat that it has cost us nearly £7,000 this half-year to repair the cables. That is a very serious item in our budget, and therefore I hope that we may go through this year with very little expenditure of that kind. We have just repaired our cable on this side, which has been hanging on a rock for 22 years. Notwithstanding this, it had continued to work without interruption until December last.

A SHAREHOLDER: On what coast?

The CHAIRMAN: The Irish coast. We had another line broken—the short line on what is called Brown's Bank; but that is now repaired, and we are in perfect working order, having re-established the duplex on our main cable. I have referred to the receipt of four letters from shareholders. I should like to point out that while we carry an amount to the reserve fund, we draw out of that fund the amount required to effect the repairs, so that, although we carry £10,000 to the reserve fund, we have in this particular case taken about £7,000 out of that amount for repairs. I think that is all I have to say to you to-day. I am pleased to be able to tell you that things are looking very much brighter, and I am quite certain that if this goes on for the six months we have now entered on we shall be able to be a little more cheery at our next meeting. I now propose the following resolution:—

"*That the Report of the Directors, dated the 7th of January, 1896, together with the Statements of Account to 31st December, 1895, annexed thereto, be, and the same are, hereby received and adopted.*"

Mr. E. M. UNDERDOWN, Q.C., seconded the motion.

The CHAIRMAN, in answer to Mr. Goodsall, said: We have adopted Dr. Muirhead's and Mr. Herbert Taylor's system of automatic transmission. These two gentlemen have put their heads together, and entered into partnership with respect to these patents, and, so far as I can remember, I do not think I have ever taken so much care in selecting the most suitable instruments as I have done on the present occasion. I had Lord Kelvin's opinion and I have had our scientific men's opinion. I am therefore quite satisfied that we have got what is a very valuable acquisition.

Mr. J. VARLEY said he thought it quite natural that shareholders should wish for a higher dividend, but during the years in which he had been a shareholder in the Company he had urged them to strengthen their position by building up a good reserve fund. They now had such a fund, and he hoped the Directors would still increase it before paying the shareholders a higher dividend. He had been a shareholder for 15 years, and he was a very large shareholder, but he was able to sleep on his shares because he knew that they had a large reserve fund. During the time that he had been a shareholder, however, he had never known their shares to be so low. They had actually £5 a share in cash, so that their cable was only valued at £3 a share, which was perfectly absurd after what the Chairman had told them.

Mr. JOHN GRIFFITHS remarked that £5. 15s. was the value of the shares in cash.

Mr. VARLEY, continuing, said that that brought down the value of their cable in the market to £2. 5s. a share. Last year he suggested that they should sell their consols, seeing the magnificent profit they could obtain by doing so. Some, however, thought at that time that Consols would go to 110—a point to which they had not reached, but they had seen them much lower. If people expected to sell at the highest and buy at the lowest points they usually did nothing whatever. He hoped that in the course of a short period they would take the profit which their Consols still showed them.

Mr. W. GRIFFITH said he thought when he read the Director's report that they were all to be very much congratulated on the great improvement which had taken place in their affairs. The large increase in their business must gladden the hearts of all who took an interest in the Company, and he himself had thought that with such an improvement they might have had an increase in the dividend. He knew that the concern was in a thoroughly sound state. They had a large reserve fund, which was also worth £50,000 more than was shown in the balance sheet. Their reserve fund was better than it was in the case of some of the companies, as a dividend could be paid out of it. He hoped that the Chairman would be able at the end of the current half-year to realise the hopes just held out to them, and that they might then receive an increase in the dividend. He quite agreed with the last speaker that their shares were far below their real value. Unfortunately, however, the general public did not always reason on sound data. They looked simply at the dividend, and concluded, rightly or wrongly, that if a dividend was large the shares were worth so much more. They would, he believed, increase the value of the shares by increasing the dividend to some extent. The Chairman had spoken of the increase in their business in the past year, and he would like to know whether the increase continued in the present year.

The CHAIRMAN: I daresay that in looking over the accounts you saw that repairs had cost us about £7,000. If there had been no amount charged this half-year for repairs, we might probably have given an increased dividend this time, but we are pretty certain now that things are tending in that direction. I have no doubt myself that we shall be able to give you a better dividend next time. I do not think it is necessary to enlarge on this point, excepting to remind you that everything is uncertain with America at the present time, and if we had to close our cable to traffic, which might be the case, we should be affected in our revenue. It is better not to begin to pay a higher dividend until one sees the way clearer. The increase in our traffic to-day is very remarkable. We are now earning 17 per cent. more, as compared with the same period last year. This is a very satisfactory state of things. I would not have said what I did with respect to the question of dividend were it not that I believe we shall realise in the proper time what I have said. Our cable, however—and I think it is well for you to bear this in mind—is getting to a certain age. Although we have repaired our cable and done a great deal to it, and it is in good working order to-day, still those who are watching cables are aware that when a cable reaches 25 years old you begin to ask questions about it. However, I am happy to tell you that we are earning at the present time the additional amount I mentioned. With respect to the sale of our Consols, I do not think it is very bad advice to sell them. We can probably invest the money at the present time, if not at a very remunerative rate, probably at a rate safer than Consols would be if war were to break out in which this country engaged. In that case Consols would go down very considerably, and I think it is well worth while to consider the question of selling our Consols which cost us about 98½ per cent., so we should get a good profit on them.

Mr. KEARTLAND enquired whether in repairing the cable to which the chairman had referred, the rock on which it had been suspended had been avoided.

The CHAIRMAN: Yes, we have taken it round. It is a most interesting illustration of the length of time a cable will wear hanging on a rock. He then put the resolution, which was carried unanimously.

Mr. W. GRIFFITH proposed a vote of thanks to the Chairman and directors for the able way in which they had conducted the affairs of the Company.

Mr. VARLEY, in seconding the motion, said he desired especially to congratulate the Directors on the reserve fund. At a critical time before, when we were threatened with war, it was said that all cables would be torn up, and the shares of the Eastern Extension Company, whose property was the finest in the world, were then quoted at about 7 on account of the possibility of their being torn up.

Mr. GRIFFITH said he thought they were to some extent protected by international law.

The CHAIRMAN: I remember once going to the Foreign Office when old Mr. Hammond was there. I said to him: "I want you to do a very important thing—namely, to get the Government to agree to the protection of the cables." He replied: "I would agree to it to-morrow, but the general who would be in command would break it." That is what we all feared, but what we think is that although in time of war the cables might be interrupted, they would not be—I do not believe it—deliberately broken if it could be helped. I think that common sense is prevailing a little more, and I believe the value of the cables is more recognised, because the moment the contest is at an end the whole thing bursts into life again. I am hopeful, therefore, that we shall not be put to any inconvenience through having our cables in the deep sea cut.

Mr. JOHN NEWTON said he believed that in the event of war the cables would be cut, but that would only be putting matters in suspense. There would be no destruction of property.

The CHAIRMAN remarked that they had ten or twelve steamers traversing the ocean doing nothing but repairing the cables.

Mr. NEWTON said he did not think it ought to go forth that cables in a time of war were in greater danger than was railway property. He was sure that the destruction of bridges on the railways would be far more disastrous than the damage which would be done to cables, which could be stopped working by one effective cut, and this could be easily repaired afterwards. He had never had the slightest apprehension that war would interfere with cable property beyond stopping the revenue for the time being of any particular cable.

The CHAIRMAN: I am very disposed to take that view also. I am obliged to you for your vote. I hope you will have a prosperous year this year, and that all these troubles will quieten down.

The proceedings then terminated.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30⅝d. per oz. (Jan. 23rd). Consols (2¾ per cent.) 107⅝—107¾ for money, 107⅝—107¾ for account; 2½ per cent. 104¼—104½ (Jan. 23rd). Stock Exchange Settling Days: Consols, Feb. 3rd; Stocks and Shares Continuation Day, Jan. 28th; Ticket Day, Jan. 29th; Pay Day, Jan. 30th.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The Directors of this Company recommend a dividend at the rate of 5 per cent. per annum on the preferred shares, and 3½ per cent. per annum on the ordinary shares, as against 2 per cent. on the ordinary shares for the corresponding period last year. A balance of £2,074 has been carried forward.

City and South London Railway Company.

The following Report of the Directors of this Company for the half-year ended December 31st last will be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Tuesday, the 28th inst., at twelve noon :—

The receipts from all sources for the past half-year have amounted to £24,554 9s. 2d., and the cost of working has been £14,638 16s. 4d., leaving a profit of £9,915 12s. 10d. Inclusive of the balance brought forward from the 31st December last, the net revenue account shows an aggregate total of £10,922 7s. 4d. After making provision for the Debenture and Debenture Stock interest, a balance remains available for dividend of £7,111 7s. 1d. Out of this sum the Directors recommend that the full dividend of 5 per cent. per annum be paid on the Preference shares, and that a dividend at the rate of 1¼ per cent. per annum be paid upon the Consolidated Ordinary Stock, leaving a balance of £1,219 16s. 1d. to be carried forward to the next account. During the past six months a further sum of £9,400 terminable Mortgage Debenture Bonds has been paid off.

A table, accompanying the report, shows the number of passengers (exclusive of season ticket holders) carried since the opening of the railway to be 30,441,609, and the receipts £222,827 2s. 3d. For the first complete half-year (30th June, 1891) the passengers carried numbered 2,412,343, and for the half-year to 30th December last to 3,172,438.

During the summer quarter of the past half-year the traffic of the line was considerably diminished by the unusual and prolonged heat which then prevailed, and since that time the traffic of the line has suffered from the entire closing of the Oval for football matches, but, notwithstanding these drawbacks, there is an increase in the receipts, and this is especially noticeable in the item of season tickets, which indicates the steadily growing confidence of the public in the convenience, safety, and punctuality of the line.

In regard to the extension of the line to Finsbury Pavement, the Directors state that most satisfactory arrangements have now been entered into in respect of the more important properties required, and are such as justify them in fully believing that the proposed extension can be carried out within the estimated time. Preparations are therefore being made for carrying out the extension without delay, and the proprietors will be asked at the extraordinary general meeting called for that purpose, out of the capital of the Act, 1893, to be then created, to sanction the issue of 20,000 Five per Cent. Preference shares of £10 each, which it is estimated will be sufficient to provide the amount required. It is intended that in the issue of these shares, arrangements shall be made that no charge will fall upon revenue in respect to the dividend upon them, until after the time at which it is estimated the extension will be open for traffic, and earning a larger sum than will be required for that purpose.

The alterations at King William-street Station, to which reference was made at the last meeting, have occupied a longer time than was expected, owing to the necessity of avoiding interference with the existing traffic ; but they are now completed, and will be brought into use in the course of a few days. The difficulty of dealing with the morning and evening traffic still continues, involving a considerable loss of revenue, but it is hoped that the additional trains, which these alterations will accommodate, will enable the press of traffic at those times to be better provided for. The additional sidings at Stockwell are now finished, and will add greatly to the convenience of the working of that station. In view of the increased number of trains to be run, seven additional carriages have been ordered, and an additional locomotive built in the Company's own shops is nearly completed. The generating plant, which is in good working order and repair, has been materially strengthened by the erection of a small engine and dynamo, which will effect a decided economy in working the traffic in the less busy part of the day. An order has also been given for the erection of a condensing apparatus at the generating station, which it is anticipated will make a considerable reduction in the quantity of coal consumed.

As the powers of the Company for the compulsory purchase of lands in connection with the Act of 1893 will expire in August next, application is being made to Parliament for a further extension of that time, and powers are also sought for the acquisition of a site for a temporary shaft in the High-street, Borough, with the view of saving expense in the construction of the junction of the new extension with the existing tunnels.

Mr. Basil Mott, the engineer of the Company, having resigned his position in order to take up an appointment in connection with the construction of the Central London Railway, Mr. P. V. McMahon, who has acted for some years as assistant engineer, has been appointed to succeed him.

Messrs. Charles Seymour Grenfell and Edwin Tate offer themselves for re-election as Directors, as does Mr. J. L. Oliver as auditor.

Waterloo and City Railway Company.

The Report of the Directors to be submitted to the Shareholders at the fourth half-yearly general meeting, to be held at Waterloo Station, London, on Thursday, the 6th prox., at 2 p.m., states that the expenditure amounted to £62,321 8s. 4d., making the total outlay £122,736 5s. 7d., at the 31st December, 1895. The works have continued to make good progress. An agreement has been settled with the South-Western Railway Company for the easements required from them for the terminus at Waterloo, and arrangements have also been made with the Central London Railway Company with respect to the City terminus. The Directors who retire are Mr. Wyndham Spencer Portal, The Right Hon. Sir Algernon West, K.C.B., and Mr. Percy Mortimer, who seek re-election. Mr. H. W. Notman, one of the auditors, also seeks re-election.

The following is the Engineers' Report :—

"We beg to report that during the past six months the works have made steady progress on both sides of the Thames. Towards the City both tunnels are in the London clay beneath the low level sewer, the Metropolitan District Railway and Queen Victorias-treet, and have reached a point about midway between Benet's Hill and Lambeth Hill, near the College of Arms. Towards Waterloo the tunnels have for some time past been driven under compressed air under Stamford-street, and are on the average about 150 yards eastward of the junction of the Waterloo Bridge-road with Stamford-street.

The total length of single tunnel driven during the past six months has been	1,635 yards
The total length of single tunnel completed is now	2,835 „
Leaving a total length of single tunnel to be constructed between the terminal stations at either end of the railway of	1,565 yards

December 31, 1895. W. R. Galbraith, J. H. Greathead, } *Engineers.*"

NEW COMPANIES, STATUTORY RETURNS, &c.

DAIMLER MOTOR COMPANY (LIMITED).—This Company was registered on January 17th with a capital of £100,000, in £10 shares, to acquire, develop or otherwise turn to account any patents, licences or concessions, to manufacture, sell or deal in motors of every description, cycles, vehicles, flying machines and carriages of all descriptions, and to carry on the business of electricians, mechanical engineers, machinists, wire drawers, galvanisers, electro-platers, &c. The first subscribers, with one share each, are : J. T. Higginbottom, W. Tees, E. Richards, H. Mobbs, J. Herbert, J. F. Vickery and P. Smith.

ELECTRIC METER COMPANY (LIMITED).—The annual return to January 3rd has been filed ; 2,007 shares have been taken up out of a nominal capital of £50,000, in £10 shares, and 2,000 of these have been issued as fully paid. The full amount has been called on the remainder.

ELECTRIC OZONE SYNDICATE (LIMITED).—The statutory return to November 29th has been filed. Seven shares have been subscribed for out of a nominal capital of £12,000 in £10 shares, but no calls have been made.

OKONITE COMPANY (LIMITED).—The annual return to January 3rd has been filed. The capital is £340,000, in 17,000 Ordinary and 17,000 Preference shares of £10 each. All the Ordinary and 16,995 Preference have been taken up, and 5,666 of each class have been issued as fully paid. The full amount has been called on the remainder.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended January 19th were £1,004, against £996 in the corresponding week of 1895, an increase of £8. The total receipts for half-year amounted to £3,041, against £3,001 for the corresponding period of 1895, an increase of £40.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The revenue return of this Company for the quarter ended December 31st last is as follows :—Sale of current for public lighting, £3,107, against £3,181 in the corresponding quarter last year ; private lighting, &c., £40,757, as compared with £26,052 ; estimated revenue from other sources, £750, as against £404 ; total—£44,614, as compared with £29,637, or an increase of £14,977. There was an equivalent of 8 c.p. lamps connected on December 31, 1895, of 195,317, an increase of 24,490, and of 21,429 as compared with 1894.

EASTERN TELEGRAPH COMPANY (LIMITED).—The coupons on this Company's Five per Cent. Debentures, due February 1st next, will be paid on and after that date by Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. Coupons must be left three days for examination.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—The payment is announced on February 1st of interest for the half-year ending January 31st on this Company's Four per Cent. Mortgage Debentures. The transfer books will be closed from the 28th inst. to 1st prox. inclusive.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 19th inst. amounted to £1,172. The amount for the corresponding week last year was £900 ; increase, £272.

ST. JAMES' AND PALL MALL ELECTRIC LIGHTING COMPANY (LTD.).—The Directors of this Company recommend a dividend at the rate of 10½ per cent. per annum on the Ordinary shares for the half-year ended December 31st last, making, with the interim dividend, 7½ per cent for the year 1895.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended January 17th, 1896, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), amounted to £2,915.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended January 15th are £2,516, as compared with £1,970 in the corresponding period of 1895. The September receipts, estimated at £3,144, realised £3,237.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED.)—The Directors of this Corporation have decided to recommend that a dividend at the rate of 9 per cent. for the past half year, making with the interim dividend already paid, a dividend of 7 per cent. for the year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 924. [No. 14. Vol. XXXVI.] FRIDAY, JANUARY 31, 1896. PRICE SIXPENCE.

NOTES.

LONGITUDINAL ether waves are developing quite a romantic history of their own. The exponents of the electromagnetic theory of light first threw them on to the scrapheap of Nature, as it were, by making their velocity infinite. Thus conveniently got out of the way, they were not likely to interfere with the normal behaviour of the transverse ether waves. Later on, someone noticed these neglected longitudinal waves, and was struck with the idea that they might fit in very nicely as an explanation of gravity. Their infinite velocity, in view of the absence of gravitational aberration, was their chief recommendation; and for a long time they seemed the only candidates for a post from which LESAGE'S ultra-mundane corpuscules and every other occupant had been summarily dismissed. But somehow or other longitudinal waves of ether did not go very far to explain gravitation; and they remained disconsolately out of work until quite recently, when an attempt has been made to put them to a good account in connection with the discovery of RÖNTGEN'S X rays. Unfortunately, in order to secure this post, it would seem that they must relinquish their property of infinite velocity, which, unless their finite velocity is practically infinite for the purpose, would seem likely to disqualify them as couriers of gravitation.

A PROBLEM which has to be solved by the engineer almost every day of his life is to determine the minimum margin of safety permissible in any given undertaking. The solution certainly involves calculations based on theoretical investigations and experimental knowledge of the strength of materials; but it also involves the results of an experience derived from lengthened use under varied circumstances. It is not as a rule difficult to find a solution when the problem is one of general engineering, but in some cases which present themselves in electrical engineering it is difficult even to state the problem fully, and this largely because of the small time-integral of experience at the command of the electrical engineer. Take, for instance, the comparatively simple job of wiring a building for the electric light. Absolute immunity from accident may be obtained in two ways: by spending no money on such work—having no electric light!!—or by spending an extravagantly large sum, z, on the work. For a certain expenditure, y, the factor of safety may be such as to bring us perilously near the danger line; while for an expenditure x, (something between y and z), there will be a sufficiently large factor of safety. The solution x is subject to a certain amount of risk, which may be covered by insurance. If the risk accepted is fairly covered by the premium, the profit on the transaction should be merely a fair dividend on the capital employed, and not the whole amount of the premium paid minus the proper proportion of establishment charges. Now it has been stated more than once recently, as an evidence of the excellence of certain rules, that not a single shilling has as yet been paid on account of loss through the failure of work conforming to these rules. Doubtless this is a most happy state of things, but how does it look from the insurer's point of view? Is this not a case of requiring a factor of safety which implies an expenditure too near the maximum value z, whilst the *premium* has been fixed for a factor of safety obtainable by a minimum expenditure near the value y? Why pay the premium at all? When one considers the sublime indifference shown by the insurance companies as to the condition of the gas piping and gas fittings in a house, it strikes one as somewhat illogical that electric light wiring should be so closely looked after. If the insurance offices could be brought to see that leaky, carelessly-run gas piping is, to say the least, no less a source of danger to life and property than jerry wiring, it would be fatuous to complain of rules which result in good work being done instead of bad. So long, however, as the insurance offices are afraid to treat a powerful interest with the same severity that they treat a comparatively weak one, they lay themselves open to the charge of unfair dealing and deprive themselves of the unanimous support they would otherwise receive from the electrical industry in raising the present standard of indoor wiring.

AT a discussion which recently took place at the American Institute of Electrical Engineers, the engineer of the Boston Edison Illuminating Company's station criticised English supply station equipment practice, as compared with German. He was in favour of using two or three large engines in conjunction with a storage-battery plant, and opposed the English plan of using many small engines. Engineers in this country will be astonished to hear that "the actual economy of these small engines running under the best possible conditions is less than the economy of the large engine run under the best possible conditions, and a storage battery of 75 per cent efficiency." To begin with, this statement is not correct. At least, disregarding any defects in American small engines, we

Digitized by Google

know that high-speed engines can be built for 200 H.P. or thereabouts, which will have an economy of steam not more than a shade lower than the best of the large 800 H.P. or 1,000 H.P. low-speed engines; the question of batteries being left out altogether. But, in the next place, the statement is misleading since it does not cover actual practice in supply stations. To ensure that the engines in a station equipped with two or three large engines should always run at the best possible load, or even at as good a load as in a station more subdivided, a prohibitively large battery plant would have to be used. Even as it is, at some of our best stations where there are as many as from 9 to 13 engines besides batteries, it is found to be impossible to get a higher engine load factor than about 80 per cent. To attain even this, in a three-engine station, the storage capacity would have to be enormously increased, unless, indeed, transatlantic local conditions produce a far more favourable load curve than is ever met with in this country. Engineers in other countries, before they condemn English practice—innovation as it may be—should look into our results as regards working expenses, and we feel sure that the majority of our highly-subdivided stations will bear considerable scrutiny by foreign engineers.

It was at the Chicago Electrical Congress, in August, 1893, that Mr. Louis B. Marks introduced his incandescent-arc lamp to the electrical world, and set forth the advantages of surrounding an electric arc by an inert gas at a high pressure. The life of the carbons would be increased, and it was claimed that for all practical purposes the new form of lamp was as efficient as the older type. Since that time there have been other inventors of enclosed arcs, who have prophesied that the end of the ordinary arc was at hand. It was with feelings of considerable curiosity, therefore, that we recently lighted on an article in the *Electrical Engineer*, of New York, entitled: "The Marks Ventilated Enclosed Arc." Further investigation revealed that Mr. Marks had foresworn the use of a high-pressure jacket of inert gas, and had replaced this by a glass globe, throughout which the free passage of air currents is encouraged. The arc is certainly enclosed; but, so far as the influence of air on it is concerned, it might just as well be surrounded by an ordinary globe. In fact, there are many ordinary arc lamps in the market in which ventilation is not so complete as in the new pattern of Marks enclosed arc lamp.

The reasons which are put forward in justification of this interesting departure are not less instructive than the change itself. The shortening of the arc for a given potential difference due to the enclosure of the arc by a high-pressure gaseous jacket has made it necessary to work such an arc at unusually high potential differences, and the absence of an oxidising agent develops a flatter crater and a stumpier negative tip. Moreover, we are told that when the enclosed arc is worked at ordinary potential differences, unsteadiness of the light results, and mushrooming occurs on the negative tip. It is to avoid these difficulties that Mr. Marks has adopted the construction just described.

Glancing recently through the pages of an esteemed German electrotechnical contemporary, our attention was arrested by an article with the, to us, startling heading of "Zur Frage der Vagabundiren Ströme," which, being hastily interpreted, might mean "The Question of Current Vagabonds." This was obviously an article intended for the columns of the German equivalent of the *Poor Law Journal*. A perusal of the text revealed, however, that the question under discussion was not the growth of contemporary pauperism, but related to what are known in the Anglo-Saxon world as "stray" currents. The palm for picturesque vigour must certainly be awarded in this instance, as in most others, to Teutonic electrotechnical nomenclature. At the same time, it seems rather hard upon return traction currents, which, after all, are only seeking the electrically best, shortest and least-crowded path home to the negative pole, that they should be thus brutally characterised and handed over, as it were, to the tender mercies of the German police.

The British Association and American Units.—We warned England long ago, says the *Electrical Journal* of Chicago, "that the usurpation of electrical units by the British Association would lead to war."

Aluminium and Electrolysis.—Mr. Arthur H. Vesey announces that the proprietors of *Aluminium and Electrolysis* have decided to postpone the publication of the paper for two months in order that an interesting number may be submitted to the public.

Royal Society.—The following Paper was down for reading yesterday: Prof. G. M. Minchin, F.R.S., "The Electrical Measurement of Starlight. Observations made at the Observatory of Daramona House, co. Westmeath, in January, 1896. Second Report."

Electric Traction for Leeds.—At a meeting of the Highways Committee of the Leeds Corporation on Thursday, it was resolved to adopt, subject to the approval of the Council, the recommendations with regard to electric traction contained in the Report of Dr. John Hopkinson, briefly summarised in our issue of January 10th.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
St. Thome—Loanda	January 15, 1896 ..	January 26, 1896
Puerto Plata—Martinique ...	December 19, 1895 ...	—
Perim—Obock	January 2, 1896 ...	—
Odessa—Constantinople	January 17, 1896 ...	—
Aden—Zanzibar	January 26, 1896 ...	—

Municipal Telephony.—A number of business men in Manchester are about to ask the Corporation to inaugurate an independent telephone system for the city. A Committee has been formed, and the requisition has already received the signatures of 1,000 of the leading firms in Manchester. It will be presented to the Lord Mayor in the course of a few days.

Steel Tubular Telegraph Poles.—The wrought-iron and steel tube makers in the Midlands have been informed that the Government is considering the advisability of adopting metal poles for the construction of telegraph lines instead of the timber ones now in use. The particular pole which is believed to find favour with the authorities is a corrugated galvanised one, lately patented in this country and abroad.

Electric Bicycle Lamp.—A compact little bicycle lamp has recently been brought out in America. It consists of a 2 c.p. low voltage incandescent lamp mounted in a parabolic reflecting case, in the lower part of which is a small alternator of simple construction. Power is obtained by means of friction gear from the upper part of the front wheel. It is not clear from the descriptions which have reached us how the great ranges in speed which the bicycle would have are prevented from affecting the brilliance of the lamp.

Electric Car Accidents.—The method of preventing electric street tramway accidents adopted by the Steinway Electric

Digitized by Google

Railway, of Long Island City, N.Y., is worthy of general adoption. In accordance with an agreement made a year ago, *Engineering News* says, prizes of $25 each were paid each motorman and conductor who got through the year without an accident to his car. The full prize was given to 98 men, and lesser prizes were given to 94 men who had served less than a year, over $4000 in all being distributed.

"The Western Electrician."—Our Chicago contemporary, the *Western Electrician*, in its issue of January 11th, comes out with a quite unnecessary apology for "a day's delay and the slightly changed appearance of the paper," due to a fire which took place on the previous Saturday, and by which the composing room was completely gutted. We diagnosed the condition of our contemporary as "normal" until it gave us an insight into the very abnormal conditions amid which its issue of January 11th had been brought out.

An Electrically-Driven Punching Machine.—An electrical punching machine has recently been brought out by Messrs. Craig and Donald, and is now being used in one of the shipyards of Messrs. Denny Bros. The motor is of 18 B.H.P., and runs at 700 revolutions per minute. Two holes are punched at a time at each end of the machine, the diameter of each hole being 1in. By a throwing-out gear it is possible to make each end work independently of the other end. A description and illustration of this machine are given in a recent issue of *Engineering*.

Expiring Patents.—On Sunday next will expire Patent No. 513, of 1882, granted to Mr. Vernon Boys for "Improvements in Electric Meters." The patent is for an invention for "measuring and registering the electricity passed through a conductor by counting the oscillations of a balance wheel governed by a torsion spring, the torsive length of which is determined by a lever acted on by the attraction of an electro-magnet having its coil in the circuit of the conductor."——On Thursday next will expire Patent No. 563, of 1882, granted to A. J. Jarman for "Improvements in Arc Electric Lamps." The patent specification describes a lamp with an adjustable solenoid controlling a clutch mechanism.

The Controller and a Substitute.—"The series-parallel controller," says the *Electric Railway Gazette* of New York, "has but two really economical running points, the others involving the introduction of wasteful resistance, and that this is duly recognised by engineers is shown by the extensive calculation and experiment which are now being carried on with a view to provide such methods of regulation as will render the induction motor suitable for railway purposes. The experiments are being pushed principally along the lines of varying the number of poles presented to the armature, and machines have been designed with as many as 24 poles, but have been abandoned on account of self-inductive action."

A Physical Millennium.—According to an article in the *Electrical World* of New York, Nikola Tesla thinks that "the discovery which would do most to better our condition would be the demonstration that the earth's electrical charge can be disturbed, and thereby electrical waves efficiently transmitted to any distance without the use of cables or wires." According to the article immediately following this, in the pages of our contemporary, Edison says that "the discovery or invention which would do most to better the conditions of life" would be "the production of electricity direct from coal." The moral is that every enthusiast believes his own pet scheme to be a panacea for all the ills the flesh is heir to.

Subway Work in Brooklyn.—The annual report of the Commissioners of Electrical Subways in the City of Brooklyn shows that the aggregate length of electric conductors of all kinds within the city limits is 20,371 miles, of which 3,599 miles were added during the past year. Over 12,000 miles of wire is placed underground or suspended beneath the elevated railways. The underground conduit now in place is 126 miles in length; length of single duct, 343 miles. Until specific appropriation is made the wires of the police and fire departments cannot be placed in subways. "The work of the extension of the telephone system during the year," the report says, "has been unprecedented, owing in part probably to the adoption by the Company of cheaper rates for a certain class of service, such as the ordinary householder wants, and partly to the natural inevitable growth of the system."

Novel Application of the Trolley System.—The proprietors of a mine in Michigan are considering a novel application of the trolley system of electric traction. The mineral from the mine is freighted down an inclined railway, the length of which is 15 miles and the fall about 800ft.; and the empty trucks have to be hauled up this inclined track on a parallel line. It is proposed to utilise the weight of the heavy freight trains to drive dynamos on the axles, these acting as brakes and transmitting their current to a trolley system, from which it would be taken by motors on the light empty trains. Given a sufficient gradient and a large enough difference between the weights of the full and empty trains, the plan appears to be perfectly feasible.

"Terrestrial Magnetism."—We have received the first number of this new quarterly journal devoted to geomagnetism, which is published by the Chicago University Press, under the auspices of Prof. A. A. Michelson and the editorship of Dr. L. A. Bauer, with the co-operation of a long international list of magneticians. The first issue consists of 54 imperial octavo pages, and contains an article by Prof. Schuster "On Electric Currents Induced by Rotating Magnets and their Application to Some Phenomena of Terrestrial Magnetism," and an article in German by Prof. A. Schmidt, of Gotha, entitled "Die Verteilung des Erdmagnetischen Potentials in Bezug auf Beliebige Durchmesser der Erde"; also a reproduction of Halley's earliest equal-variation magnetic chart, and several pages of reviews, letters, notes, &c

Erratum.—In our footnote to Mr. J. E. Ritter's letter on "An Eccentric System of Electric Supply," on page 425 of our issue last week, it was incorrectly asserted that the heat developed by a superposed continuous and alternating current would *not* be the same as the sum of the quantities of heat separately developed by each of the currents. A valued correspondent has pointed out that the time integral of the square of the composite current is, in such a case, equal to the sum of the separate time integrals of the squares of the separate currents. It will thus be seen that the heat generated by 10 continuous amperes and 10 alternating amperes flowing through the same conductor is only half that generated by 20 continuous amperes flowing through that same conductor.

Röntgen's Rays.—The great interest taken in the results of Prof. Röntgen's experiments has led the proprietors of the *Photogram* to arrange a special issue of that journal entirely devoted to this subject. The issue, entitled the *New Light*, was published yesterday.—The excitement which Prof. Röntgen's discovery has created generally has resulted, according to the *Berliner Tageblatt*, in the formation at Berlin of a society for scientific photography. Amongst the 40 members with whom the society has started we note the names of Profs. E. Wiedemann, Kohlrausch, L. Weber, and Dr. Ebert. The aim of the society is not only photography, but the investigation of related optical phenomena. The erection of a laboratory is in contemplation, and monthly meetings will be held at which lectures and experiments will take place. At first the *Photographische Mittheilungen* will be the organ of the society. At the first meeting of the society a series of new shadow photographs, taken by the Röntgen method, was shown and discussed. All further information can be obtained from Herr Fr. Damke, Photographic Laboratory, Technical High School, Charlottenburg.

The Waste of Steam in Small Pumps.—According to the *Journal of Gas Lighting*, a remarkable disclosure respecting the wastefulness of steam, and consequently of fuel, in a large factory where additional pumps and other machinery had been put up promiscuously to meet requirements as they arose, has been made by Mr. Charles E. Emery, in a Paper read at the last meeting of the American Society of Mechanical Engineers. Mr. Emery was called in to advise an Oil Company in New Jersey how to reduce their fuel account; the consumption of coal for raising steam having risen by degrees to 64,000 tons per annum. Mr. Emery found that besides a large amount of steam required here for heating purposes, a great deal was

Digitized by Google

needed for pumping, pressing, and so forth. It was found that many of the steam pumps were using as much as 240lb. of water per net horse-power per hour; and only in exceptional cases could one be found to take so little as 80lb. of feed water per horse-power. Mr. Emery recommended the establishment in the works of a number of power stations, in which would be erected good high-pressure non-condensing engines operating power pumps to take the place of the scattered steam pumps; the exhaust from such engines to be distributed by mains for heating purposes. Electric transmission was also recommended for reaching outlying parts of the works. The recommendations were adopted, with the net result of reducing the consumption of fuel by one-half.

The Central Station Industry in France.—In its issue of January 25th, *l'Industrie Electrique* publishes the sixth edition of its provincial central station table. In January, 1895, France, exclusive of Paris, possessed 328 electric supply stations; to-day the total is 438. The increase in the total horse-power has not, however, been very great; the figures for the 378 stations which sent in returns showing a total of 47,712 H.P. (126 H.P. per station), as against 39,420 for the 328 stations at work last January. The 378 stations may be classified as follows:—

Motive power.	No. of Stations.	H.P.
Hydraulic	182	11,665
Hydraulic and steam	48	7,422
Steam	128	26,802
Producer gas	6	206
Town gas	13	1,605
Petroleum	1	12
	378	47,712

System.	No. of Stations.	H.P.
Continuous	293	31,935
Alternate	75	14,927
Polyphase	4	850
	372	47,712

Worm-geared Motors.—A statement that worm gearing, if used for power transmission in electrical work, should be employed only in conjunction with low-speed motors, has brought out a statement from E. Kolben, of the Oerlikon Engineering Works in Switzerland, who, in a contribution to a German publication, says that high-speed motors should be adopted in such cases if the best results are to be obtained. He points out, says the *Engineer*, that a great prejudice against worm gearing has hitherto existed, on account of its having been regarded in the old text and handbooks as an inefficient means of transmission. He believes, moreover, that much depends upon the construction of the gearing, and refers to tests recently carried out by Professor Stodola, of the Zurich Polytechnic, with the ordinary double-thread worm gear of the Oerlikon Engineering Works. The worm was 80mm. (3·15in.) in diameter, had a multiple ring bearing, and engaged with a worm wheel having 28 teeth, the wheel being of bronze, 373mm. (14·7in.) in diameter. The whole of this gear was placed in oil in a cast-iron box. The gear was coupled to a 20 H.P. electric motor, and the brake was applied on the worm-wheel shaft. At 1,500 revolutions, a useful performance of 21 H.P. was given on the brake, the efficiency amounting to 87 per cent. Herr Kolben is of the opinion that the efficiency with the motor fully loaded will increase even beyond 90 per cent. if the speed is high, the worm made of tool steel polished, the worm teeth of bronze, and the friction of the whole mechanism on the starting of motors at full load is reduced by having the pressure taken up by starting discs arranged on both ends of the worm. These results are in accord with tests of worm gear made some years ago by Mr. A. Reckenzaun.

Mr. Edward Weston and "Electricity."—In its issue of January 15th the *Electrical Engineer* of New York, on the authority of the *New York News Bureau*, states that "Mr. B. E. Greene, editor of *Electricity* (New York), has retired from the management of that paper, and hereafter, including this week's number, *Electricity* will be issued under the direction of Mr. Edward Weston, electrician, of the Weston Electrical Instrument Company, of Newark, N.J., who has associated with him Mr. C. D. Shain, eastern agent of Siemens and Halske." In a leaderette in the same issue our New York contemporary has the following:—"The announcement which we made last week as to the intention of Mr. Edward Weston to enter again the larger field of general electrical manufacture is one that has naturally been received with much surprise and interest. Of late years Mr. Weston has made an international reputation for himself as a designer of beautiful and accurate instruments, but it was not easy to see why he should so utterly abandon the scenes of his earlier successes. His work in electro-deposition and plating, his efficient and finely-regulating dynamos, his methods of distribution, his incandescent lamps—including those with the tamidine filament—all attested his master hand. We are glad to welcome Mr. Weston back to electrical engineering, and can assure him that there is plenty of work awaiting his skill and genius. The reports that Mr. Weston intends also to devote himself actively to electrical journalism are the sheerest absurdity. Mr. Weston is a creator, not a critic or historian, and it is needless to say that he is perfectly willing to leave the drudgery of newspaper work to those who, while they record his progress with satisfaction, will not dream that they too are inventors." We do not suggest that these two statements are irreconcilable, but their reconciliation certainly would appear somewhat difficult.

"Capital Expenditure" Supplement.—This week's supplement of capital expenditure in electrical supply undertakings in this country is complementary to the table issued with our January 3rd number, and completes the set of supply station statistics usually published with this journal in January. It will be seen that a large increase in capital expenditure has taken place during 1895. No reference is made to the borrowing powers possessed by local authorities, which are in many cases far in excess of the sums set out in the table. Bedford has borrowing powers up to £39,000. Blackpool contemplates borrowing a further £30,000, Cheltenham a further £10,000. Henley has borrowing powers up to £46,110. At Harrogate most of the contracts have been let, and a loan for £29,000 has been obtained. Hampstead Vestry is applying for a new loan of £30,000. Hammersmith's expenditure of £7,200 is quite preliminary. Islington's total estimated outlay when the station is fully opened in March is £90,000. Manchester has borrowing powers up to £250,000. Newport (Mon.) is applying for borrowing powers up to £40,000. In cases like Croydon, St. Helens, South Shields, Wakefield and Wigan, considerable capital expenditure has been incurred, as is the case also at places from which we have been unable to obtain information. At Shrewsbury the station is actually in operation, but it is too early to obtain the figures. It may, therefore, safely be estimated that a total of about £10,000,000 is invested in electric current supply undertakings in this country. It will be seen from the supplement that 27 stations are in progress, and of these Islington (London) is announced for opening in March next. In several other cases, the contracts for buildings, plant, mains, &c., have been given out, and in all others the preliminary stage of operations is in a forward state. In some cases, moreover, considerable capital expenditure has been incurred, but the figures are too approximate to justify inclusion in this list.

The Alternate-Current Transformer.—At the commencement of his second Cantor lecture on the "Alternate-Current Transformer," on Monday evening last, Dr. Fleming showed a very pretty hydrostatic model illustrative of the action of the alternate-current transformer. It consisted of a U-tube half full of water, the legs of which were of different diameter the column of water in each leg, when that in one was exposed to pressure and suction, rose and fell, the amplitude of motion in each leg being in inverse ratio of the diameters of the two tubes. To show the high self-induction of the primary of a transformer when its secondary is open, a 50-volt lamp was connected *in series* with the primary of a small transformer connected across 100-volt wires. The lamp only glowed dimly, but on momentarily closing the secondary, it immediately flashed up, owing to the annulment of the self-induction of the primary. After reference to the formulæ for eddy-current losses given by Prof. J. J. Thomson in *The Electrician* of April 8, 1892, and the results given by Prof. Ewing in *The Electrician* of April 15,

Digitized by Google

1892, Dr. Fleming presented his own modification of them in the following useful practical formulæ for core losses, viz.:—

$$E=\left(\frac{t n B}{10^8}\right)^2, \text{ and } E=1{\cdot}4\times10^6\left(\frac{t' n' B'}{10^8}\right)^2,$$

where t = thickness of sheet iron in mils, t' ditto in inches, n = frequency, B and B' = respectively the induction per square centimetre and square inch, E = eddy current losses in watts per cubic centimetre of iron; E' = ditto per pound. If we denote the hysteresis losses in watts per cubic centimetre and per pound respectively by H and H', and the corresponding *total* loss by T and T' we get:—

$$H=\frac{{\cdot}0032\, n\, B^{1{\cdot}55}}{10^7},$$

$$H'=\frac{{\cdot}88\, n\,(B')^{1{\cdot}55}}{10^9},$$

$$T=\frac{{\cdot}0032\, n\, B^{1{\cdot}55}}{10^7}+\left(\frac{t n B}{10^8}\right)^2,$$

$$T'=\frac{{\cdot}88\, n\,(B')^{1{\cdot}55}}{10^9}+1{\cdot}4\times10^6\left(\frac{t' n\,(B')}{10^8}\right)^2.$$

The eddy current loss in a good transformer iron, he said, should not exceed 0·07 watt per pound. According to J. J. Thomson and Ewing it was no use to employ thinner iron sheet than $\frac{1}{100}$th of an inch, and it was no use laminating the core at all unless the laminæ were at least as thin as $\frac{1}{25}$th of an inch. Steinmetz's $B^{1.6}$ law of hysteresis loss was, the lecturer said, in very fair agreement with the actual facts over a range of induction from zero to 10,000 C.G.S. units. The maximum permissible hysteresis loss for transformer iron was about $\frac{1}{3}$rd of a watt per pound at 100 ∼ with $B=2{,}500$. Curves were then given showing the effect of plates of different thicknesses on core-losses, the eddy-current loss increasing rapidly with the thickness of the plate, the hysteresis loss but slightly. In ordinary practice plates about 0·014in. thick were used. Various patterns of core plates were then exhibited, and the serious effect of bad magnetic joints alluded to in connection with the Ganz type of core with butt joints resulting in a "power factor" of 0·4 and 0·5 at low loads. The meaning of the term "power-factor" and the importance of this quantity were then explained. Power-factor = true power : apparent power. To the electric supply engineer the power factor of the transformers connected to his mains was an indication of the fraction of the total current sent out from the station which is paid for. Ewing's molecular theory of magnetism was then explained and illustrated by a model, and the lecture closed with a reference to the respective claims of open and closed circuit transformers; the latter type had the advantage of a higher "power factor," and the core losses were practically no greater for any given output power.

A Telephone Inventor.—A Boston newspaper representative recently interviewed Mr. Francis Blake, of telephone transmitter fame, and the following extracts are taken from a reprint of the interview published in the *Western Electrician* of January 11th. Mr. Blake admitted that for two years he had done no serious work. "Since my invention of the long-distance transmitter," said he, "I have not invented anything of particular commercial value." The inventor related his experiments in arboriculture, and confessed that coffee-roasting had formed a recent diversion. Next to his mechanical experiments and amateur photography, Mr. Blake is most interested in the improvement of Keewaydin, the name which he has given to his fine estate at Weston, ten miles from Boston. In regard to what he proposed to accomplish he was silent. "I think it is a great mistake," he said, "to talk about what you hope to do. Do it first, and then talk about it afterward." "I don't see," he said, when questioned in regard to the future of sound transmission, "what more is to be attained in the short-distance telephone. You may see evidence of this in the fact that men are no longer attempting to improve upon it as they were once." Questioned as to the discovery which bears his name, Mr. Blake said: "My attention was first directed to the Bell telephone in 1876, when Prof. J. E. Hilyard, a prominent member of the Board which awarded Mr. Bell his prize for the telephone at the Exhibition, explained to me the instrument which he had examined. I was very much interested, for I had made a special study of electricity while I was attached to the astronomical service of the Coast Survey, where I was engaged principally in the telegraphic determinations of longitudes in various parts of the United States, Europe and South America. Very soon after this I constructed a pair of hand telephones myself, very much like Mr. Bell's, which I still have in my possession. I devoted a great deal of time—many months—to experiments designed to ascertain the best proportions for various parts of the telephone—the size of the coils, diaphragms, methods of clamping, &c. I constructed a microphone, after an article by Prof. Hughes, which appeared in *Nature*, I think. By experimenting upon the microphone I was finally able, after a great many trials, to construct one which, when placed in the circuit of my small hand telephone, produced most satisfactory results. I well remember that on the first test of this instrument every word was distinctly understood, while even a whisper was perfectly transmitted. I then became satisfied that I had the broad principle of an important invention, and from that time on I devoted myself to a series of careful experiments to perfect the details and to discover the methods of adjustment of the parts necessary to produce the most nearly perfect results." Mr. Blake's life has been a remarkably varied and eventful one. In 1866 he secured an appointment in the United States Coast Survey. He was in the employment of the Government for twelve years. He was stationed for astronomical duty at Harvard, and also in Texas and Louisiana. He was also engaged as assistant in a party organised for a hydrographic survey of the Susquehanna river, the west coast of Florida and the north coast of Cuba. Mr. Blake was sent to Steubenville, Ky., to observe the solar eclipse, of August 7, 1869, and was ordered to determine the astronomical latitude and longitude of Cedar Falls, Iowa, and St. Louis, Mo. He was appointed astronomer to the Darien exploring expedition. Three years after this he was offered charge of the transit of Venus expedition to the southern hemisphere, but he was forced reluctantly to decline. For some time Mr. Blake was stationed successively at Brest, the Imperial Observatory at Paris, and the Royal Observatory at Greenwich. This was the occasion of the third and final determination of the difference of longitude between Greenwich, Paris and Cambridge, and all the observations were made by him.

Contemporary Electrical Science.—*Wiedemann's Annalen* for January contains many somewhat startling contributions.——Electric Waves are, as usual, the staple product of German-speaking physicists, although Boltzmann and Planck deliver two separate attacks upon modern "energetics," chiefly as expounded by Ostwald. It seems that the mechanical theory of the universe and scientific materialism, so ably attacked by the great chemist, will not surrender without a struggle. Planck himself also writes upon the resonance of electric waves, and shows how the distribution of energy in a resounding circuit may be calculated from Maxwell's equations. Elster and Geitel contradict the rumour that positive electricity is dissipated, like negative, by the action of light. They show that it is all due to a secondary action upon the platinum cathode as soon as it gets coated with a layer of vapour from the liquid sodium-potassium alloy forming the anode.——V. von Lang has an interesting little Paper upon The Diminution of Resistance of a Light Contact between Carbons or Metallic Terminals under the action of the slight electric waves produced by an electric gas lighter or by an electrophorus. The experiment with carbon is easy, but that with metals requires great care in order to avoid the slightest concussion. With Jaumann's sensational Paper on Longitudinal Light we have already briefly dealt (see *The Electrician*, January 24th, p. 417). It will be interesting to see how Maxwell's equations will fare in these days of breathless activity and rapid progress. ——Leo Arons discusses the curious fact that Alternate-Current Arcs are much more difficult to produce with metallic than with carbon electrodes, and suggests three possible explanations. The carbon may be better suited to sustain the necessary heat through the zero points owing to its smaller thermal conductivity. Or the gases which carbon always will evolve up to its own death, in spite of all precautions, may undertake this function. Or the metallic oxides are in the way. Perhaps further experiments will bring more light.

ON THE RAYS OF LENARD AND RÖNTGEN.

BY DR. OLIVER LODGE, F.R.S.

In the days of Gassiot and other early workers on the discharge in rarefied gas it was the stream from the anode that chiefly excited attention. It is this which displays the well-known gorgeous effects which used to be shown at nearly every scientific conversazione.

The discharge starts indeed from both terminals, but that from the cathode proceeds but a very little way, while that from the anode proceeds nearly the whole length of the tube, even though it be many metres in length, travelling with something comparable to half the speed of light, as has been proved by J. J. Thomson.

As exhaustions were improved the discharge was seen to change from a bright continuous streamer into a beaded or striated column, and it was the striæ upon which attention was then chiefly directed, as well as upon the outer or "second" dark space which had been so full of interest to Faraday. De la Rue, Spottiswoode and Moulton added to our knowledge of the occurrences in this stage.

The first, so far as I know, effectively to call attention to the surpassing interest of the events in the inner dark space, most closely surrounding the cathode, was Hittorf; but there can be no question that these dark-space phenomena were developed and expanded, and pressed home to the meanest apprehension most completely, by the highly skilful and brilliant experiments and exposition given to the Royal Society and the British Association in 1879 by William Crookes. Assisted by Mr. Gimingham, and working with vacua higher than anything previously attained, the discoverer of the radiometer irradiated the whole subject with a flood of light and set it on its present basis. The inner dark space was now broadened out so as to fill the whole tube: it was shown to consist of flying electrical particles, and everything exposed to their impact became brilliantly luminescent. Between Hittorf and Crookes must lie the discovery and the effectual vitalisation of that now well-known phenomenon—the cathode ray. This constitutes the third stage in the development.

Then appeared Hertz: certainly one of the most marvellous combinations of mathematical and experimental power that we have seen in recent times. Not a word has been said in excess of the fame due to him; since Clerk Maxwell's death Physical Science has had no untimely loss like his to deplore. He found that the cathode rays impinging on German glass coated with gold leaf and other kinds of metal made the glass phosphoresce not only where it was uncovered, but, at sufficiently high exhaustion, also where it was covered with metal; discovered, in fact, that flakes of metal were more transparent to cathode rays than were flakes of mica of equal thickness.

Before and after his death his *quondam* assistant, Dr. Lenard, took the matter up, and with consummate experimental skill conducted a series of investigations that essentially started our till recently newest era. His ambition was to get the rays out of the vacuum into the open air, and at Hertz's suggestion he "glazed" his vacuum tube with an aluminium window for the purpose. Very thin, very small, and very delicate was Lenard's window, for it had to be thin enough to be cathodically transparent, thick enough not to leak air through imperceptible holes, and strong enough to resist the whole pressure of the atmosphere. The cementing of a metallic window on to a tube intended to be worked at such high exhaustion that an induction coil spark would prefer 3cm. of ordinary air rather than traverse the tube was no easy matter. However, the difficulties were overcome, the aluminium-closed vacuum tube was constructed, cathode rays of great strength were started inside it and directed on to the window,—if necessary, being deflected thereon by a magnet; and outside, in the otherwise perfectly dark region in free air, on the other side the partition, the air itself, as well as the window, were seen to be glowing with a faint phosphorescent light. Strongly fluorescent materials held in this region were, of course, brilliantly lighted up: and photographic plates and films were quickly blackened. The rays from the window were not a mere prolongation of the cathode stream; they started afresh in all directions, as light does when a parallel beam impinges on a minute orifice. The skin and the eye could feel nothing of these rays, but fluorescent and photographic materials were abundantly sensitive. Lenard conceived that he had here a novel kind of ethereal radiation; but whether it consisted of very minute transverse waves, analogous to light but much higher up in the spectrum than those usually called ultra-violet, or whether it consisted of waves not transverse, or of something else not waves at all, he did not pretend to decide. Certainly material bodies introduced into the rays behaved in a very different manner from the way they behaved to light. Dense bodies were rather opaque, rare bodies were rather transparent; and nothing to do with electric conductivity seemed effective in connection with these rays as it was with light—nothing but density seemed much to matter. Hence certainly they were not Hertz waves or anything submissive to Maxwell's equations,—conductors must be opaque to *them;* unless, indeed, the molecules or their interstices could be dealt with instead of coarse groups of them, in which case ordinary conductivity ceases to exist, and abnormal transparency can be fairly explained. Hydrogen was found to be the most transparent of the gases by Lenard, but if it were squeezed till it was as dense as oxygen, then it behaved just like oxygen, and so on. Metals and non-metals of equal density were about equally opaque, roughly speaking. Moreover, nothing was dead opaque or clearly transparent; all substances were turbid, like milk. They did not stop the rays by reflection, but by diffusion. After going through a sufficient thickness of matter, the beam, limited and made definite by a suitable diaphragm, became fuzzy and bordered by a sort of aureole when received on a fluorescent screen. But this turbidity, he is careful to say, is not increased by dust or suspended gross matter. It is a true *molecular* turbidity, and indicates that he is dealing with something of molecular magnitude.

Aluminium was more transparent to these rays than quartz, *and a shadow photograph was taken to illustrate this, by putting a sensitive plate in an aluminium-fronted box,* and then interposing in the path of the rays, between the source and the sensitive plate, a couple of rectangular strips of quartz and aluminium, partially overlapping. The plate, on development, showed four regions; the darkest when it had not been screened at all, except by the walls of its perfectly light-tight box, the next darkest where the shadow of the aluminium rectangle had fallen, lighter still in the shadow of the quartz strip, and almost unaffected in the portion screened by the two overlapping materials. All this, it must be noted, in 1893 and 1894.

One more observation I give in his own words, as translated in your Volume XXXII., p. 576: "On replacing the aluminium window by one of glass it was found possible to repeat all the essential experiments with equal success. But the aluminium window remains the more suitable; not that it is more transparent, but because aluminium is opaque to light and more easily manipulated than glass of equal thickness."

Thus Lenard had actually got the rays to come out of a plain glass vacuum tube, provided it was highly enough exhausted and with thin enough walls.

The writer well remembers trying, in 1894, to get the Lenard rays out of a not unsuitable but rather thick vacuum tube, in stupid ignorance of this just-quoted result, and failing. Failing simply by reason of insufficient pertinacity, as it now turns out, for this very tube is by him now, and with it he has been able, aided always by his admirable assistant, E. E. Robinson, to repeat Röntgen's results and get good photographs without trouble through a quarter-inch of wood and a sheet of aluminium, provided something like half an hour's exposure is allowed. The tube is a large one, without electrodes, and to excite its fluorescence the coil should be provided with knobs, which are allowed to spark directly into each other; the tinfoil coatings on the glass then act as Leyden jars, and give impulsive rushes into the tube.

Lenard tried whether the rays would charge a body electrostatically, but they would not. On the contrary, they rapidly discharged a body already charged; and this equally, whether that initial charge were positive or negative. This experiment probably influenced him to conceive of his rays as something ethereal, and to deny that they were streams of electrified

Digitized by Google

particles bombarded off his window by the impact of the cathode stream. He considers that the passage through metal has effectually filtered all the truly *electric* properties from his rays; and, accordingly, he is prepared to find, as he does, that they neither decompose nor liberate gases from anything, as the unfiltered cathode rays themselves do. True, the filtered rays, which it is now convenient, at least for the present, to style Lenard rays, are able to precipitate chemical actions in sensitive silver gelatine films; but, when it is remembered how surpassingly responsive these are to a luminous stimulus, it may well be conjectured that the Lenard rays act only in a physical and secondary manner by the intervention of some kind of phosphorescence (a term much better replaced by "*luminescence*," in accordance with the suggestion of E. Wiedemann, whenever there is nothing of the nature of phosphoric combustion.)

Getting the rays into exhausted tubes he finds them travelling several metres in a straight line, and keeping clear and sharp, provided the tube is sufficiently exhausted, the last traces of mercury vapour being, in this instance, lessened by application of a freezing mixture after days of pumping. In such a tube no cathode rays could have been *generated*, but the Lenard rays are just in their element. Must it not be then, he asks, that this element is really the ether?

Now comes the crucial experiment: are the Lenard rays deflected by a magnet? Experiment answers they are. When the medium is turbid and produces an aureole the experiment is not distinct, hence Lenard did not succeed in either proving or disproving deflection in common air, but in a "complete" vacuum the deflection is clear and sharp; in a partial one, when there is a little aureole, the hazy patch is deflected more than the central spot, and is, in fact, spread out into a kind of "magnetic spectrum."

Varying the pressure of the gas causes no alteration in the deflection of the central spot, it only affects the position of the deflected aureole or diffusion caused by the presence of gross matter; the clear central unaltered spot, he argues, must be something ethereal. How, then, can it be deflected by a magnet? Light waves are not thus acted on. By no direct force, he conceives the answer to be: by a modification of the ether, caused by the magnet, a modification which twists the ray aside somewhat after the fashion of Faraday's rotated plane of polarisation; and in proof of this he adduces an experiment of Hertz to show that there is no reciprocal force acting on the magnet, in other words, that the ray is not *forced* aside, like matter, but skewed aside by an ethereal twist.

The theoretical views of an experimenter are not to be lightly scorned, even when they fail to accord with our well-based prepossessions. A man who lives among phenomena is to be listened to, for he often feels instinctively more than he can logically establish and justify. In this country, however, with all due respect to the illustrious experimenter, his theoretical views have not found favour. The writer, as well as other more competent judges, have felt, and consistently expressed the conviction, that the fact of magnetic deflection pointed to a stream of electrified particles; it might be to a kind of Grotthüs chain, or electrolytic radiation, but at any rate to something material, not ethereal. Arguments based on occurrences which go on in the presumed absence of matter, say in tubes exhausted to the hundred millionth of an atmosphere, are very weak, because every cubic millimetre of such "exhausted" space still contains a hundred thousand million fully-fledged molecules. The marvel is that phenomena in space so crowded with substance can yet be so strikingly different from those which occur when the matter is made, say, a million-fold denser. Nothing, therefore, seemed conclusive *against* the radiant-matter idea, and the fact of magnetic deflection seemed almost conclusive in its favour.

Once more let us ignore theoretical views at present and stick to facts. Lenard found that although varying the gas in his *observing* space left the main magnetic deflection unaltered, so long as it could be clearly observed, yet that a variation in the exhaustion of the *originating* space, where the undeniable cathode rays were impinging on his window, produced a notable effect. An increase in the exhaustion of this vessel was found to decrease the deflecting power of a given magnetic field on the Lenard rays outside. Hence, if the exhaustion could be pushed to extremes it may be urged as probable that the magnetic deflection would almost cease.

(A remark must be interpolated here to the effect that the last-quoted fact lends strength to the idea of electrolytic radiation, or at least of radiant matter in some form, as opposed to an etherial process.

For conceive an atom of mass m charged with the quantity q flying with velocity v through a magnetic field of intensity H. It is equivalent to a current $q\,v$, and it experiences a deflecting force $q\,v\,\mathrm{H}$. Hence its acceleration is $\frac{q\,v\,\mathrm{H}}{m}$; and, since this is normal to the velocity, it can be equated to the usual centripetal acceleration $\frac{v^2}{r}$, where r is the radius of curvatures of the orbit or trajectory of the particle.

Wherefore it follows that the magnetic curvature of the path is

$$\frac{1}{r} = \frac{q}{m} \cdot \frac{\mathrm{H}}{v}.$$

The first factor is the reciprocal of the ordinary electrochemical equivalent of the substance, and is known; hence the curvature is expressed in direct proportion to the reciprocal of the velocity. A lessened curvature, therefore, simply points to a higher velocity, and at sufficiently high exhaustions it may happen that a few of the molecules in the vacuum tube, under the stress of the potential gradient on their enormous charges, are moving with something approaching the speed of light. Most of them are much slower, as J. J. Thomson has indicated, but it is permissible to think of some as having excessive speed. If so, the path of such particles would be probably straight through any ordinary magnetic field such as has hitherto been applied to test them. And on the usual impact principles, of receiving and handing on motion, atoms driven away by them from the other side of a partition might be expected to receive and pass on something like this enormous speed for some distance further.)

Lenard found that there were different kinds of his rays; some of them more deflectible, some of them less; those which are more deflectible are more affected by turbidity, and soon get stopped by moderately opaque substances, but those which are less deflectible are more pertinacious in their passage through matter, and may be expected to penetrate to considerable distances, even through reasonably opaque media.

Can it be possible, the writer now goes on to ask, that Prof. Röntgen has utilised these very rays? It is evident that the apparatus at his disposal is pre-eminently adapted to exhibit Röntgen radiation, whatever it is. No other experimenter seems to have obtained such good results, unless there are some not yet widely published. Mr. Swinton, by application of immense power, has come nearest to it in this country so far, but the rays used by him do not appear to penetrate the flesh of the hand with anything like the ease that Prof. Röntgen's do. Those used by me at present are also less penetrating. They give good results with metals, but with the hand the bones hardly show through the surrounding material (the finger nails come out clearly transparent). Lenard, it appears, used something of this last sort of radiation, and matter appeared to him more turbid than it does to Prof. Röntgen. Why is Röntgen's source of rays so powerful? Is it the kind of glass, or its size, or its exhaustion, or has it something to do with the electrode? He has not yet told us the details, but it may be surmised that his Crookes tube happened to be extra well exhausted and of good German glass (English glass seems useless). At any rate, he seems to get easily what others get with difficulty. Certainly he is most warmly to be congratulated!

Once more, considering the question of the possible hypotheses, Prof. Röntgen leans to the view that they may be longitudinal ether waves. Authorities in this country are hovering between ultra ultra-violet waves, on the one hand, and longitudinal vibration on the other.

The writer only hopes that it *may* turn out a longitudinal vibration. There is a great deal to be said in favour of such a view, and on the whole it seems to the writer the most probable of the etherial hypotheses: more probable than that of extra

Digitized by Google

ultra violet light, because of the transparency of the metals. The fact that simple material *density* is the chief factor determing opacity, has a very gravitational look about it. Can it be that at last we are on the track of gravitation experimentally? Anyhow, if it be but something periodic comparable to the size of atoms, many problems of supreme interest would be in a fair way of yielding up their answers. The writer hopes at least that it may turn out something etherial, and may give a method for determining μ and K; but for the present he permits himself to doubt, and inclines to a sort of electrolytic impulsive propagation through and by means of ordinary matter, in spite of the immensely important fact that Prof. Röntgen can detect in his rays no magnetic deflectibility whatever. The clearness of his rays enables him to achieve this result in ordinary air. It is to be remembered that Lenard was only able to observe his deflections in a partial vacuum. Ordinary air was too turbid, and the image too indistinct. This experiment of no magnetic deflection of the Röntgen rays I have indeed so far confirmed as to be satisfied that any deflection there may be is extremely small—far smaller than that appropriate to any kind of known cathode rays. Perhaps it is *nil*, and if so, projection of charged particles is *ipso facto* and finally put out of court, but perhaps it is only small, in which case, as has been shown above, charged particles flying at high velocity are indicated. It would only be the most rapid particles that could get through the obstacles and imprint themselves upon the plate, and it is just these that would be least deflected. Hence, until the details of Prof. Röntgen's magnetic experiments are forthcoming, there is still a loophole for the dullest and most commonplace of all the at present conjectured explanations. Meanwhile, the possibility, even the probability, that in these rays we have a new kind of radiation, even though it be only ultra-violet so high up as to be comparable to the size of molecules, lends to these experiments a prodigious interest in the eyes of physicists, far surpassing the obvious practical applications which have gained the ear of the general public.

Liverpool, January 26, 1896.

THE CROMPTON POTENTIOMETER: ITS USE AND CAPABILITIES.—IV.*

BY W. C. FISHER, ASSOC.MEM.INST.C.E.

A brief *résumé* of the points that necessitated, and the difficulties attendant upon, the construction of such a galvanometer as that shown in Fig. 14 (*see* Article III.) might be of interest.

Six years ago, with a view to very accurate work, it was decided to investigate and obtain, if possible, a d'Arsonval galvanometer of great sensibility. Different makers' instruments were tried, and one by one abandoned as being unfit for the purpose desired, until the Carpentier instrument, with coil resuspended, as has been already described, was proved to be by far the most sensitive instrument available. Still something better was aimed at, and with that object in view, it was decided to try what strengthening the magnetic field would do. For this purpose an electromagnetic galvanometer was constructed having vertical limbs and hatchet-shaped poles, between which a Carpentier coil was duly suspended, but, as had been discovered a few months earlier by Mr. Mather, it was found that whilst up to a certain point the deflections became greater with increased strength of field, beyond that point the deflection gradually fell off as the field was strengthened, this being due, as Messrs. Ayrton and Mather have pointed out, to the presence of iron in the materials used in the construction of the coils. A remedy for the same was found by Messrs. Ayrton and Mather, and it is due to Prof. Ayrton's kindness in disclosing the process adopted that the sensibility of the instrument (Fig. 14) is to a great extent due.

During these experiments it was also found that a false sensibility could be given to the coil by so suspending it, slightly out of its true centre and slightly awry in the magnetic field, that deflection due to current in the coil was materially assisted. This effect was first observed by Prof. Eric Gerard, of Liége, who by such means obtained extreme sensibility; it led, however, to false zeros, false sensibilities, and general instability in behaviour, not the least of which was that the sensibility occurred in one direction only. The effect so produced has been termed the "Gerard effect." It prevents the adoption of a square form of coil for delicate work, which form, under certain conditions, is theoretically considered to be the most efficient in deflectional power. The ring coil was adopted as being least likely to develop this effect; assurance in that respect has been made doubly sure by the adoption of a long bifilar suspension, which would doubtless be still further improved by the

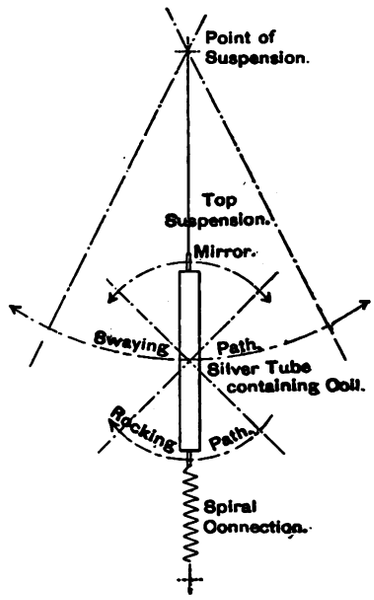

FIG. 16.

adoption of one suspension, the second connection being a spiral of very fine wire around same. The ring form of coil was first sketched out for the writer by Mr. Crompton in 1890, it being thought, next to the square-shaped coil, most suitable for the object in view—*i.e.*, maximum sensibility off zero only.

In addition to the means adopted, as already mentioned, for freeing the coil from iron and so eliminating as far as possible magnetic control, to ensure sensibility an intense field is

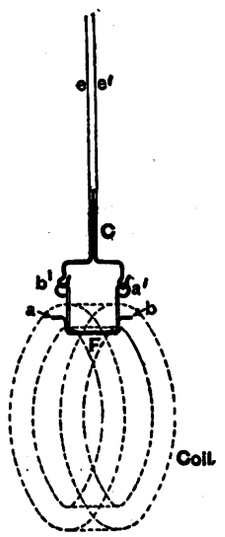

FIG. 17.—Method of Suspending Coil.

obtained by the employment of large powerful magnets having very narrow poles, so concentrating as much as possible the lines of force in the air gap, the magnetic resistance of which is decreased by the introduction of a soft-iron disc. The coil is enclosed circumferentially as much as possible by the magnet poles, so that the amount of waste winding is exceedingly small. These points, in combination with a long suspension, have resulted in the great sensibility above mentioned.

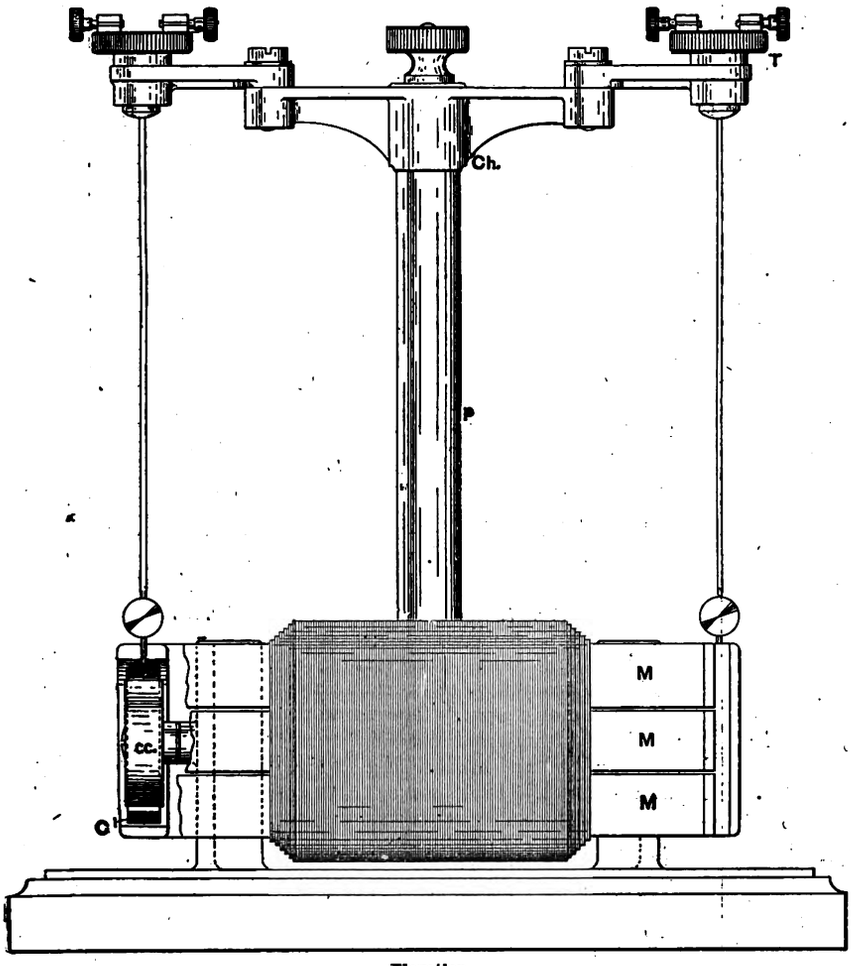
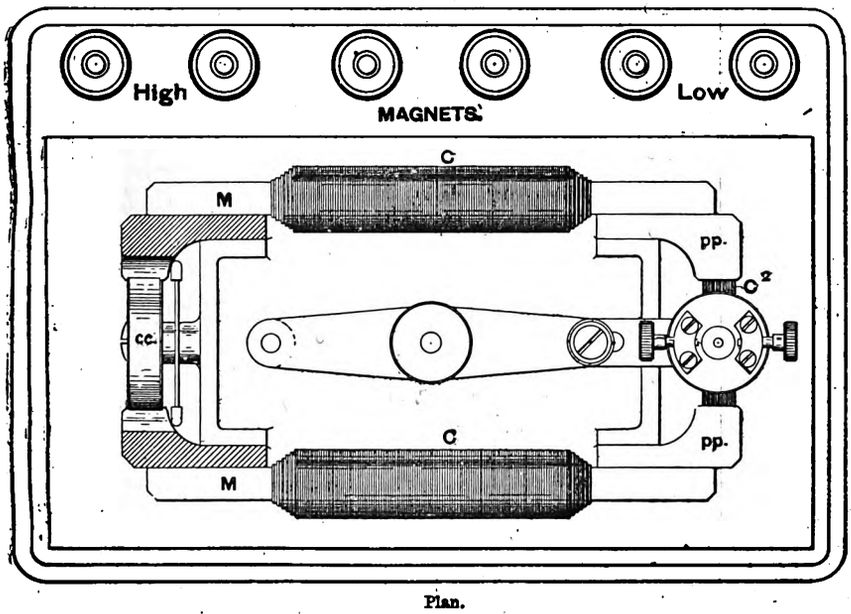
The question of vibration was one of considerable moment, inasmuch as it had to be entirely eliminated in order to obtain concordant and definite results, seeing the very minute forces that were at work, to say nothing of the effect on a delicately-balanced temper of a blurred mass upon the scale, amidst which might occasionally be seen—like the "Trotter" arc microbe—



Elevation.



Plan.

FIG. 13.

the bright image sought. The vibration chiefly to be guarded against was that due to the proximity of rapidly-rotating machinery, &c. Under such conditions, as might be expected, it was observed in the various instruments under test that coils of given weight with short suspensions more readily responded and got into step than when suspended and strained with longer ligaments. Such vibration was of a simple horizontal nature set up in the same direction as the parent vibration; it was possible at times, by altering the tension of the ligaments, to partially eliminate or even completely break up this vibration in the coil. This was, however, impossible in a coil having a short top suspension only without any bottom control; in such, a compound vibration is set up which is anything but pleasant, and which is best described by a glance at Fig. 16, in which it will be seen that in addition to a swaying vibration having the point of suspension as its centre, there is a very rapid oscillation about the centre of gravity of the coil. As might be expected, the vibrations being of different period, tend at times to break each other up; it is then that the coil so suspended has its sane moment, but an instant afterwards it is as mad as ever. A remedy, of course, is either a very long upper suspension, material alteration in the weight of the coil, or a strained bottom ligament. The latter alternative would entail a slight loss in sensibility, not sufficient, however, to influence it for practical work. It was therefore decided, in designing the special instrument required, to make it stiff in construction, to have a reasonably long suspension, and a coil of such shape, dimensions and weight which should be attached to the suspensions in such a manner as would entirely preclude any possible oscillation under the circumstances described. The result attained is all that could be desired, and the only vibration to which the instrument has been known to respond is a very slow one appearing at very long intervals of time, in some cases days passing without its being observed, and which is attributed to the slow oscillation of the house at the top of which it is at work.

For quick working, where great sensibility is not desired, a ready means of shortening the suspension was thought desirable; the vane already mentioned was therefore introduced, and is brought into action by being set at right angles with the vertical, or, in other words, placed horizontally, and lowered down the pillar between the bifilar suspensions until the requisite point is reached, where it is clamped, the point of suspension being practically transferred from the top turntable to the vane, which is wider than the slot in the former, through which the suspensions pass. In this manner it is possible to cut down the period of the coil to less than 25 per cent. and the sensibility to less than 35 per cent. These figures are, of course, dependent upon the characteristics of the coil.

The adoption of ebonite levelling screws of the shape indicated in drawing (Fig. 14), especially if the ledges be slightly undercut and occasionally wiped, has been productive of perfect insulation, which is still further increased by the insulation of both terminals and leads.

Coming to the fourth point enumerated in the necessary qualifications of a satisfactory galvanometer for potentiometer work—namely, that the coils be interchangeable, the reason for this will be explained later. In existing types of galvanometers the changing of a coil entails the removal of some part of the framework of the instrument as well, and the substitution of another framework with the new coil and *another* suspension of possibly very different characteristics. This method it was thought inadvisable to adopt, more especially as the massive construction of the instrument would not allow of its adoption economically. An easy method of attaching the coil itself to the suspensions—whose characteristics were known and remained constant irrespective of the various coils successively attached—in combination with the smallest weight

Digitized by Google

possible, led to the form of attachment shown in Fig. 17, in which it will be seen that one end of the coil is attached to the end b of the twin-wire cradle F, the other end b' of which terminates in a loop. The second end of the coil is attached to a, which also terminates in a loop, a'. The twin wires forming the cradle are, of course, insulated from each other, and are braced on to the coil; each coil accordingly has its own cradle attached to itself. The suspensions $e\,e'$ terminate in a twin coupling, C, likewise duly insulated, and to which the mirror is attached; the ends of the coupling are bent, as shown, into hooks, which engage in the respective loops of the coil cradle; the changing of a coil is, therefore, a matter of small moment, being merely a question of hooking or unhooking, which is easily performed with ordinary care without injury to the suspensions, which, though delicate and fine, are double, and will stand an almost incredible strain without breaking.

In order to obviate the necessity of constantly changing coils, a double instrument, shown in Fig. 18, was devised. It consists of a rectangular base, supported upon insulating

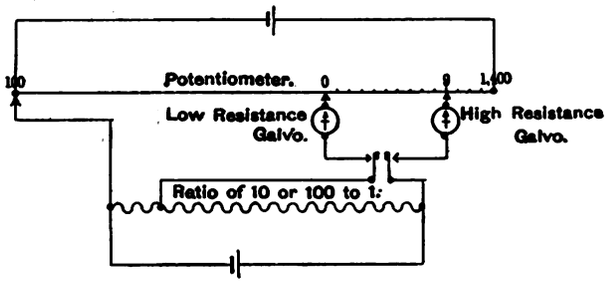


FIG. 19.

levelling screws, having two brackets cast upon it, upon which are fixed the compound permanent or electro-magnets, having suitable pole pieces and cores, as shown. The field may be regulated at will by means of the magnetising coils, and also, when necessary—by means of a yoke—the galvanometer might be made into a single limb instrument with one intense field.

The two coils, one of high the other of low resistance, are each suspended from turntables similar to that shown and described in Fig. 14. These are supported on adjustable arms attached to the cross head of the central pillar. It is of course apparent that the instrument is suitable for many purposes exterior to potentiometer work, but in conjunction with that instrument for ratio and other work it is well adapted, being connected up as in Fig. 19, from which it may be seen that

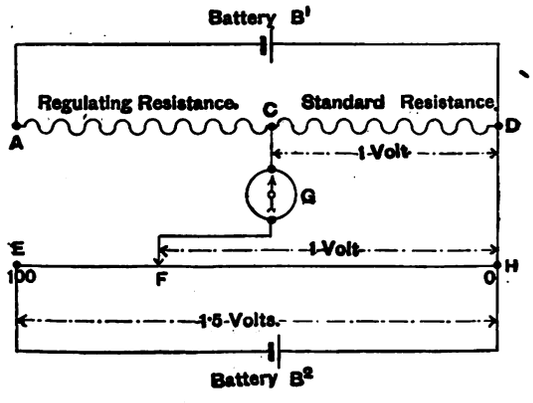

FIG. 20.

simultaneous readings may be taken if necessary. It might be pointed out that whilst these galvanometers were designed nominally for potentiometer use, they are pre-eminently adapted for ballistic work.

The necessity for changing the coils of the galvanometer may not be apparent to many, but observant operators will have noticed a considerable difference in sensibility and behaviour of the galvanometer under apparently identical conditions. The reasons for this are not far to seek when one ceases to think of potential only, and turns one's attention to what takes place when current flows through the galvanometer. Then one instantly sees that dependent rather on the characteristics of the test made, the conditions governing the deflection of the galvanometer are not equal with equal differences of potential in the *potentiometer*. That is to say, with a given galvanometer, and with identically the same E.M.F. at the terminals of the potentiometer, a given want of *balance* when measuring the E.M.F. of a Clark cell, and an entirely similar want of *balance* when

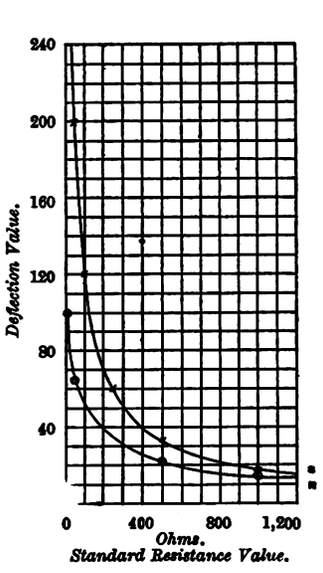

FIG. 21.

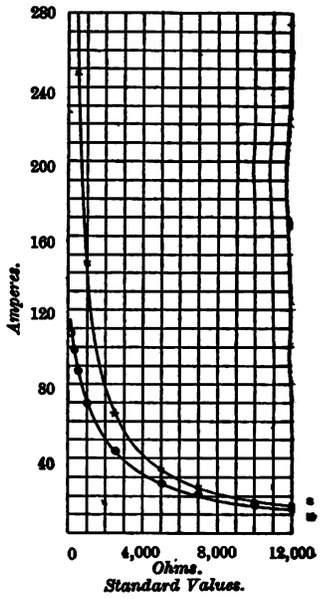

FIG. 22.

measuring the E.M.F. at the terminals of a low standard resistance is not productive of the same amount of displacement of the galvanometer spot. The same thing is apparent when comparisons of high and low resistances or E.M.F. over high and low resistances are made. Fig. 20 will perhaps more easily explain matters. In it we have the simple conditions under

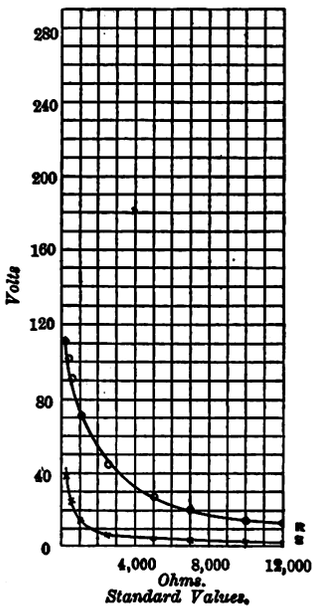

FIG. 23.

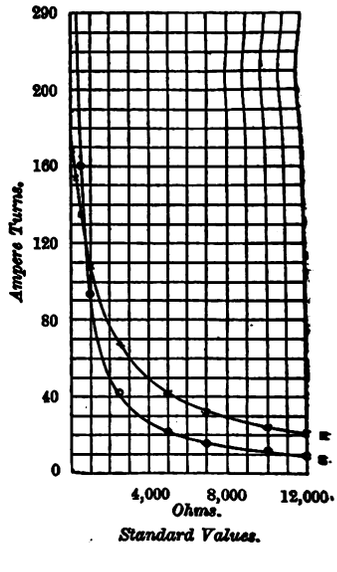

FIG. 24.

which two coils, one of low, the other of high resistance, were tested. As shown, the circuits consist of, first, the battery B', maintaining constant potential at ends, and consequently current through A C D.; second, the battery B^2, maintaining constant potentials across and current through the potentiometer E F H. The points H and D are connected together as shown. The points C and F are also connected together through the galvanometer G.

So long as one volt is maintained across C D and F H respectively, there is no flow of current through the galvanometer; but if the point F be moved we instantly have difference of

Digitized by Google

potential set up between C and F, and consequent flow of current through the galvanometer coil, the volume of which, with given displacement of the point F, would roughly be dependent upon the resistance of the circuit G C D H F.

In the experiments made with the two coils mentioned—one of which was ten times the resistance of the other—a constant minute want of balance was maintained at F, whilst at C D, although a constant difference of potential of one volt was maintained—as was also the case at F H, with the exception of the minute difference mentioned—the value of the standard resistance C D was altered, and value of deflections produced by each alteration duly noted in the case of both coils. The curves given in Fig. 21 show graphically the deflections so obtained. The curve indicated by the letter S being that produced by the low resistance coil, and that indicated by R being that of the high-resistance coil, these symbols hold good throughout the series of curves. It will be observed that the greatest deflections, as might be expected, take place when the value of the standard is low and the current flow through the galvanometer consequently high, the deflection of S, for the same reason at these values being very much in excess of R; as the value of the standard was increased the deflections diminished naturally with increased resistance of circuit G C D H F, becoming approximately equal at the very high values of resistance. So much for the deflectional values. Unfortunately, however, the comparison does not end here, for the behaviour of the coils has to be considered. In the early

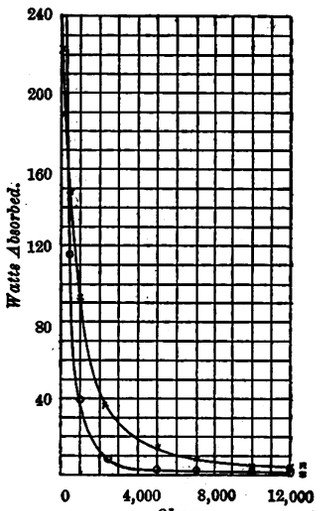

FIG. 25.

part of the curves, whilst the current flow was great, S, the low-resistance coil, sprang to its full deflection at once, whilst R moved very slowly, eventually creeping with difficulty to the points indicated. On the other hand, as the value of the standard resistance was increased and the other end of the curve attained by successive stages, we find R—the high-resistance coil—getting steadier and quicker, whilst the low-resistance coil becomes more and more erratic and uncontrollable, swaying about with little or no stability or decision. A study of the conditions and force at work in conjunction with diagram shown in Fig. 20 is productive of the following curves, which in themselves are sufficiently explanatory of the behaviour of the coils.

In Fig. 22 we have the current values plotted horizontally upon the vertical lines corresponding to the values of the standard resistance in circuit; as might be expected, the curves so produced are practically coincident with those of deflection, with high standard values being almost equal, and gradually increasing as the resistance in circuit is lowered, S attaining a far higher value than R.

In Fig. 23 are represented the curve of E.M.F. values at the terminals of the galvanometer coil; as is natural, the curves change places, R—the E.M.F. at the terminals of the high-resistance coil—being considerably above S throughout.

Fig. 24 gives the curve of ampere-turns in the coils, and it is at once noticeable that the two curves cross each other very quickly, the high-resistance coil R speedily attaining to double the number of ampere-turns in S, which was the predominant partner at the commencement of the curve. The ratio of convolutions in the two coils being approximately $2\frac{1}{2}$ to 1, a glance at Fig. 23 makes it very manifest that the curves must cross, for the higher current values of R, if multiplied by 2·5, will bring us slightly below the value of S at those points. On the other hand, when we multiply the lower current values of R by 2·5, we get very much above S.

The same thing is apparent in Fig. 25, which represents the curve of watts absorbed in the coils. The curve again crosses quickly, for whilst, by glancing at Figs. 22 and 23, we find at the commencement of the curves we have *one-fourth* the current, we have three times the E.M.F. in R that we have in S, whilst at the other end the current in both coils are approximately equal, but the E.M.F. at the terminals of R is 10 times that of S.

The above are but two examples of a series of tests made with different coils and from which certain deductions have been made and particulars obtained. Into these it is not the writer's intention to enter at present; it is only interesting to point out from the above that at the time when the low-resistance coil S is quick and decisive in its movement, and the high-resistance coil R is slow and creepy, it (S) has approximately 1·6 the number of ampere-turns, and 1·5 the watts absorbed in R. On the other hand, at the other end of the curve, when S is unstable and wavering, and R is quick and steady, it (S) has approximately but 0·5 the number of ampere-turns, and 0·1 the number of watts absorbed in R. From the above it is plain that for very accurate work it is necessary to have a coil suspended in the galvanometer which, under the conditions of test, is most suitable both as to sensibility and speed of working. For ordinary testing this is, of course, unnecessary, as the degree of accuracy is not so great, the forces at work are not so minute, nor need the galvanometer be so sensitive.

The writer has already mentioned the use of a millivoltmeter, and the partial success attendant thereon. It is upon this point that its weakness is apparent; the resistance usually of the coil itself is low, and whilst answering admirably when in use with a low resistance standard, the moment a Clark cell or high resistance comes into circuit its sensibility is gone.

HOUSE-WIRING.

DISCUSSION AT THE INSTITUTION OF ELECTRICAL ENGINEERS.

On Thursday evening, January 23rd, the discussion was commenced on the Papers on house-wiring read before the Institution of Electrical Engineers on November 28th last by Messrs. Sam Mavor and Fred Bathurst. The following is an abstract of this discussion:—

Mr. W[illegible]PEL said now that the existing rules of the Institution for wiring were on the point of revision, the two Papers under discussion had an additional importance, apart from the mere relation they had to the two particular methods advocated by their respective authors. He endorsed cordially the point urged by Mr. Bathurst as to the principal obstacle to the general adoption of electric lighting. It was undoubtedly the expense of wiring the building. Those of them interested in the supply of electricity were doing their utmost to reduce the cost of supply; the lamp manufacturers, as to the expense of lamps, were doing likewise, and yet, to judge from the tone of the remarks made at the recent Board of Trade Conference, an attempt was being made by some of them to increase this cost of wiring, through raising the standard of insulation to an unnecessarily high pitch. By all means let them protest against shoddy work, but do not let them put on needless refinement. Some of the rules of supply undertakings stipulated for as much as 75 megohms per lamp—quite an unnecessary standard. It was satisfactory to think that the persons really interested—namely, the insurance companies—were so far much less drastic. The Phœnix stipulation was 12·5 megohms per lamp, and twenty-five other leading companies stipulated that the leakage was not to exceed one twenty-thousandth of the total current, which at 100 volts equalled two megohms only per ampere. The present rules of the Institution were one five-thousandth of the total current, equal to half a megohm per ampere, or $\frac{1}{10}$th part of that first mentioned. This appeared to be quite adequate. He regretted to see, also, a tendency amongst the engineers of low-tension systems to force a 200-volt supply upon the consumer. Wiring contractors would do well to join the consumers and to protest emphatically against this practice; at any rate until such time as absolutely reliable and cheap 8 c.p.

Digitized by Google

lamps were obtainable for this pressure. Meantime it was sufficiently difficult to get 100 volt 8 c.p. lamps which would stand burning at an economical efficiency. It must be remembered that for economical reasons the renewals of 8 c.p. lamps should be less frequent than lamps of larger candle-power, as there was a definite ratio between cost of current and renewals. The life of an 8 c.p. lamp should be about root two times that of a 16 c.p., assuming that each lamp cost the same. The first question occuring to all of them was, Did the methods advocated by the authors tend towards economy in first cost? He was afraid that that question was not answered by any reliable data, in fact there was a noticeable absence in both Papers of any figures as to cost. Perhaps the authors would give some data in their replies. In urging the advantages of his system Mr. Bathurst said that he saved on the insulation, which was half the cost of the wire. But did he maintain that his tubes were supplied and fixed for the same price as the much-abused casing or compo. tubing? He thought this could not be so, more especially as Mr. Bathurst spoke of the necessity of trained workmen. In his (Mr. Geipel's) opinion the extensive use of casing was largely due to the fact that there were always plenty of joiners to be had who did the work without special training. In speaking of the advantage of high insulation of his wires, he was afraid Mr. Bathurst forgot that the really weak points were in the switches, cut-outs and fittings. What Mr. Bathurst meant by the actual strain C^2R he could not understand. He could not follow Mr. Bathurst in his statement that rust in pipes was unfavourable to insulation. Rust was a better non-conductor than unoxidised iron. He had listened with great interest to Mr. Mavor's description of his well-thought-out system of concentric wiring, but he hoped that the members of that Institution and the Fire Insurance Companies would not be alarmed at Mr. Mavor's somewhat pessimistic remarks and warnings as to the necessity for greater stringency. He could not at all agree with Mr. Mavor as to the unsightliness of wiring in the present system; there were numbers of houses in London where not a casing was visible. It was useless to attack the existing method on the score of unsightliness; cost alone was its vulnerable point, and unless the cost of the concentric wiring was about 50 per cent. less than it was about a year and a-half ago, he was afraid that system was not ready yet to help them. It was possible that by abolishing the insulation of the outer conductor the concentric system might become cheaper than casing. Indeed, he was of opinion that the Board of Trade might go a step further and dispense with the insulation of the "outer" of all concentric low-tension distributing mains. It might be necessary to slightly insulate the outers of the feeders to obviate telephonic interference and electrolysis, but the difference of potential between any parts of the distributing network was so small that there appeared little necessity of insulation, especially as the "outer" was, even when insulated, invariably at earth potential. With such a system a considerable saving in first cost could be made, while Mr. Mavor's concentric system with uninsulated outer would work well in with it. As to the soldering of all contacts, that necessitated the use of a soldering iron whenever a fitting or switch required disconnection or connection to the circuit. Was not this an objection, as compared with the readily-made mechanical contact? He agreed entirely with Mr. Mavor's remarks as to the importance of what he described as grouping the branch fuses at distributing centres, and he considered that the method should be made compulsory with all systems of wiring, especially as it involved no increase in first cost. He also agreed with Mr. Mavor's strictures upon the bayonet-joint lamp holder so much in vogue, and he would ask if any of the members could second his experience, which went to show that the Edison screw socket was a better holder? It certainly appeared to overcome Mr. Mavor's objections. Mr. Mavor admitted that a fault might be caused in his wires by a nail for example, yet he proceeded to argue that he might sink his wires in the plaster, as it was never necessary to remove them. He could not agree to that. The compo. tube provided a means of repairing the wires in such cases without destroying any decorations.

Mr. HANCOCK said it afforded him great pleasure to see the prominence given lately to iron piping, and also that there was a general idea about that the time had come when they should make a move from their old friend casing. He ventured to think on examining the iron pipe system before them, that although it was a step in the right direction, it might possibly be carried a little further. His firm was not altogether sure that insulating the pipe and reducing the insulation of the cable was exactly the right thing. In the first place, by putting the insulation inside the pipe they reduce its capacity a great deal. In the second place, they were not at all terrified with the thought that, as some people said, the life of vulcanised rubber was but three years. If that were the case, he would like to ask Mr. Frank Bailey, for instance, whether, in the case of the hundreds, and even thousands, of pounds worth of vulcanised cable under his control he calculated that the depreciation was 33⅓ per cent.; and he would like to ask Messrs. Henley and the Silvertown Company the same thing. Without laying any particular claim to being the first to use iron-piping, he ventured to think his firm had been to a certain degree concerned in promoting its introduction. They were aware that for some years past there had been a feeling that there was room in the electrical world for more of an engineering spirit, so to speak. Casing was not entirely satisfactory; it did not apply to all the requirements they were justified in asking of it. They knew that there had been on the market for some time past various iron pipe systems, but somehow or other no one had cared to take the plunge. But they were gratified to know that since they determined to introduce it into the Commercial Union Buildings and the Guardian Buildings and other places, it had increased in favour. The point was, that in iron piping they found a system which gave them practically everything they asked for. First of all, it was a system which could be put in whilst the building was going up; if the builder liked he could make his mortar on top of the electric light installation. Also the ubiquitous carpenter could not drive his nails through the electric light pipes, which was a considerable advantage. They found that they had with iron pipes, although there were certain drawbacks, a system which enabled them to put in all the pipes while the building was going up, and which enabled them to draw in the cables the last thing, and so start with an installation which was perfectly new, and not one which was three-parts worn out before it came into use. They also found that if anything should happen to the wire the contractor could draw the cables out again. Coming to the question of insurance, he was very much afraid that the public had been under the impression that because an installation had been passed by an insurance inspector it was safe and nothing could happen. It was a pity it could not be made known, or at all events driven home to the public in some way, that the insurance companies did not undertake the functions of a consulting engineer. They considered that if the premium now paid covered the risk, well and good, if not it would be raised unless certain additional precautions were taken. There were one or two points he would like to mention in connection with the declaration they were usually asked to fill up. In the first place, in some of the Companies' forms they had to answer this question, "What excess of current will the conductors safely carry?" He ventured to say no two members of the Institution would have the same opinion on that subject. They generally evaded the question by saying the current density was so much to the square inch, and leaving it to the discretion of the inspector to say whether that was enough or not. He would suggest upon this point that the Institution should draw up clear and concise rules; the present method was unscientific and wasteful. In the smaller sized cables they might run up to 2,000 to the inch, but often it was not safe to exceed 500 to the inch. What they wanted was a definite table which could be referred to at once, and they might say the Electrical Engineers have gone into the matter and say for such-and-such sized cable you may put a certain amount of current through and no more. Naturally as they got up to the higher side of the scale they would be guided by the consideration of temperature, and as they got lower down the scale all they would have to consider was the fall in voltage for a given length. Another question often asked was the length of cut-out proportional to the E.M.F. That, too, was rather a difficult question to answer. In the first place no standard was laid down for them, and they had to choose an arbitrary standard of their own. Taking the Metropolitan Electric Supply Company as an example, they brought into the house 2,000 volts and transformed down to, say, 200. It was evident that if they considered a cut-out on the secondary should be three inches long, then the cut-out on the Metropolitan circuit should be 5ft. long. There was something wrong there. On the other hand if the Metropolitan cut-out represented a length of four or five inches, the cut-out on the secondary should be one-fifth of an inch. Passing on to what was a burning question of the moment were they to have 50 volts, 100 volts, or 200 volts in their houses? It was a question capable of being looked at from many points of view. If they looked at it from the point of view of the central station engineer they would say at once: have 200 volts. If they looked at it from the point of view of the ordinary contractor who had to take what fittings he could get on the market at the moment, and did not want to spend too much on cables, they would say 100 volts. If they looked at it from the point of view of the consumer, he thought they would say, probably, considering the life of the lamps and the question of convenience, 50 volts. Many people said the last-named was old-fashioned. He ventured to think it was in some points of view, but it had many advantages. With 50 volts under ordinary conditions it was amazing what the life of lamps was at the moment. There were many places where they had had lamps burning three or four years, going on and on, and never going out. He did not say they were in use every day. With 100 volts their experience was mixed. When they got up to 100, what might be called the limit of convenience was reached. That was to say, although the consumer might save a little at times by going up a little higher, he did not think any advantages counterbalanced the consideration of the life of the lamp. At the present moment they must run in London under very trying conditions. He thought that as yet it was rather premature to advocate 200 volts. They were told that when they had experience in the matter they would think rather more of it; they were told the life of the lamps was something remarkable; they were told they were portable and did not break in transit, and several other things. But he still maintained that 200 volts was in the experimental stage. It had to come, but the makers of fittings were not ready for it. Those who were using it at the present moment were doing a most useful service. There was another point. When they put up the voltage to 200, it was an admirable thing from the central station engineer's point of view; they increased the capacity of their mains and the efficiency of their lamps, but they were doing the consumer no good. With regard to the three-wire system, they were told it was impossible, or next to impossible, to get a shock across two outer wires. But, although station mains were in such wonderfully good condition, curiously enough the outer mains sometimes did go to earth, and also on many circuits people had not the confidence in the continuity of the supply that they should have. The result was that they would have a gas fitting somewhere in the neighbourhood, and it would happen sometimes the fittings themselves got in contact with the circuit. The result was that somebody took hold of the gas fitting and got a shock direct through to earth.

Mr. J. H. M'LEAN said he should like to speak from the point of view of the central station engineer. They had heard a great deal about details in connection with wiring, but his opinion was that even with the old-fashioned wooden casing they could have a great deal better wiring if more attention were paid to the work. The wiring affected them to a terrible extent; he did not think they half realised the extent to which it affected them. They (central station engineers) had to make their bread and butter by running out current to the consumers; it was not their place to look after the other side of the business, but they were expected to do it. They were expected to inspect and pass the wiring of the premises to which they were supplying current, and it sometimes happened in Oxford that six or seven

STATEMENT OF CAPITAL EXPENDITURE IN ELECTRIC SUPPLY UNDERTAKINGS

To DECEMBER 31ST, 1895.

In the following Table the figures have been checked by the parties concerned, except where shown in *italics*, and in these cases a figure has been arrived at from the best available sources. † Indicates that the Supply Station is not in operation on 31st January, 1896. **N** Indicates that no information as to capital expenditure is obtainable, notwithstanding repeated applications, or that such information as is to hand is not suitable for this Table. Where a dash is inserted either no reliable figures can be given, or no capital expenditure has been incurred.

Date Supply commenced.	District supplied.	Owners of Supply Station.	Amount exp'nded to Dec. 31, 1895.	Owners of gas works in district.

The above shows that the amount of capital expended in Electric Supply Undertakings throughout the country is as follows :—

By **Companies**	5,618,336
„ **Local Authorities**	2,383,507
Total	£8,001,843

In our issue of January 18, 1895, the total was given as £7,189,173, showing an increase to date of £812,670. But it may be stated that the figures are now much more reliable than hitherto, and, in the case of the Supply Companies especially, the relation of subscribed capital to actual capital expenditure is now more clearly defined. In addition to the above large sum, schemes for the establishment of electric supply stations are under consideration by a number of Local Authorities and Companies (many of whom have already obtained the necessary Parliamentary powers), involving a large outlay, and a glance at the above list will show the number of stations which have come into operation all over the kingdom; and, therefore, what great progress has been made in the popularisation of electricity for lighting and power purposes since January 1, 1892, at which date only 4 Local Authorities and 17 Companies were supplying current.

Digitized by Google

or a dozen installations were going on at the same time. If there were six or seven miles between each and 100 steps to climb, as was the case in some of the colleges, and they were expected to look at every bit of wiring that went in, it was clear they would not have much time to look after the Company's work. This was a serious point. If they neglected the work and a fire occurred, the credit of the concern was at once called into question. Looking at it from the personal point of view, he wanted to know where his credit came in. He would like to see the fire insurance companies paying a little more attention to their own business, and leaving the station engineers to pay more attention to theirs. It very often happened that the work was finished before they received the application form, and customers would not allow them to lift up their floors and pull about their walls and ceilings to look at the wiring, and they had to content themselves with a casual inspection and test. They had been shown all sorts of tubes and all sorts of joints and connections, but he could show them just as good things with the old wooden casing. How many of those joints and connections were behind the walls or under the floors? The previous speaker, who had spoken of 200 volts, said some things that were true, and some, he thought, which were not quite true. He should like to see 200 volt lamps, but he was inclined to think that in some cases if 200 volts were turned on the light would not be at the lamps. It would be somewhere else. He was glad to hear at the Board of Trade Conference that a little more power was to be put into their hands; at present they had only to be "reasonably satisfied" that all was right. He was glad to see one clause inserted, that if the insulation fell below a certain point they were bound to cut the installation off. He would cut them off! With regard to the insurance of buildings, at the present time the insurance companies were threatening to raise the premiums on central stations. He wished they would go to the consumers and leave the stations alone. They had spent a large amount of money on iron and steel buildings, with flagged floors and steel and iron supports, and perhaps had not as much wood in the stations as would equal his own weight, and yet the insurance people were going to increase the premiums to 2s. 6d. or 3s. 6d. They were insured at Oxford for over £20,000, and it would be a serious thing for them if the insurance were raised three or four times.

Major-General WEBBER said this question of insurance was one which was coming very close home to them, especially in connection with the fact to which the last speaker had referred, that the fire insurance companies were so irrational as to propose to raise the premiums on buildings which were constructed they might say practically incombustible, while they were overlooking the great fact that electric lighting, when properly carried out, was rendering fire risk much less than it was before. There was a very large field for the electric light which, on account of the practical prohibition of the insurance companies, had not yet been occupied. In all their seaport towns there were great warehouses where the fire insurance went up to from 7s. 6d. to 15s., and in consequence of the owners of those warehouses being told that if they displaced the present means of lighting and put in the electric light they would get no reduction, they did not care to go to the expense of changing. If the insurance companies employed as inspectors men who were thoroughly masters of the subject, no doubt they would reduce the risks on that great mass of buildings, and many of the owners would in that case adopt the electric light, but at present they had no object in doing so. He thought if the insurance companies did not take some steps to reform their ways and to reconsider and study the subject as they ought to do competitors would grow up who would take the trouble to understand the diminished risks due to electric light, and companies would be brought into existence who would insure at a premium considered from that point of view, and in that way as the spread of electric lighting installations proceeded they would get a very large business indeed. This was a matter which the financial and insurance world might well turn their attention to. In connection with all these systems of wiring, he might say that it was even possible to wire their houses in a more simple way than either by casing or tubes, and although it might be that he should be called old-fashioned, he would mention the case of his own house, where electric light had now been in full use for ten years. They carried it out by the conductors being stapled to the face of the wall with saddles 3in. apart, and wherever the lead of the conductor of the opposite pole crossed beneath or above it to reach a point it was simply supported by a little sheet of ebonite made in the shape of a saddle, which provided an insulation of not more than $\frac{1}{8}$ of 1in. These conductors has been painted over, and painted over, but of course had not been subjected to violence, and there had never been a short on any part of them. He did not mean to suggest that they should wire their houses in that way, but pointed it out as a good practical example of wiring which was at the time exceedingly economical, and was more so now. It came out at 18s. per point. The wires were not disfigurements; the decoration was over them and might at any time be removed and the wires replaced.

Mr. W. E. LANGDON said they were all indebted to the authors of the Papers for not only having brought under their notice the special systems advocated in those Papers, but what was more important, for having raised this very important question of wiring. He did not go so far as the authors in their general condemnation of wood casing. Where it was carefully employed it was, in his opinion, calculated still to be of considerable service. There was no question, he thought, that wires encased in metal tubing were safer than those in wooden casing. Still the wooden casing lent itself very conveniently to surface wiring where they had to deal with buildings which were already established. The "factor of cheapness" would always enter in, and hence the cheapest method would be employed to a greater or lesser extent. But there was one point with respect to this wooden casing which he would like to mention for consideration, and that was that the wooden casing was provided with two grooves, one for the positive and the other for the negative wire. These grooves were a certain distance apart. Now, the general practice was to place a screw or nail between these two wires, so that eventually, when the insulation might become impaired, these nails or screws would tend to assist any short-circuit that might happen to come across there. In his opinion the use of any metal between the wires in the casing should be most carefully excluded. A rule has been adopted by himself for the Midland Railway for some time past that where wires were placed above ceilings or under floors only wrought iron tubing should be employed, and that the wooden casing should be only employed subject to approval on the face of walls where it was under observation, and possibly that regulation adopted elsewhere might be of service. It occurred to him that this was not entirely a question of conduit or casing, but one perhaps that had a more important side to it in the question of wiring or joints. He had had pointed out to him recently some samples taken from a large installation. The wiring was carried out by a recognised, trustworthy firm, and one which had had a great deal of experience. A great many joints were dry joints, and he thought he might say that in every instance they were found to be insulated with nothing but adhesive tape. Now, if they got that condition of things with a firm which carried out a work, not a contract, but a work paid for at the cost with a certain percentage thereon, what were they to expect on cheaper jobs where there was a fixed price and where the contractor, of course, desired to keep the cost within the amount of his contract? It seemed to him that there was the crux of the question. How were they to insist on or obtain a better state of things? Mr. Mavor, in his Paper, if he remembered rightly, threw out a suggestion as to the inspection by the fire insurance company, that the several insurance companies should combine together, and should employ a man versed in the matter, who should be able to give his whole attention to it, and so exact a better state of things or cause the rejection of the consumer's connection. Well, let them consider: could that be carried out in all towns? He was afraid it would not be. It was an excellent suggestion, but there were many towns where he feared there would be a difficulty in securing the services of such a man, and, of course, such a man would require to be properly paid. But he would like to suggest whether it would not be more to the interests of the supply companies themselves to institute such a branch, to establish an officer competent for the duty who should be empowered to inspect every installation as it progressed. They might say the supply companies had the power now to reject any installation with which they were not satisfied; but the only means of satisfying themselves at present was by a cursory examination or by testing the connection.

Mr. H. C. DONOVAN said, so far as his experience went, every system was more or less good, if the persons who worked the system had an aptitude for detail. If in putting up an electrical installation proper attention were paid to detail then they would get a good installation; but if they neglected detail in any respect they were liable to create causes of loss of insulation.

Mr. B. H. ANTILL said he would like to be allowed to draw attention to what he believed was the most conspicuous example existing of "open-wiring"—viz., that which was to be found at the British Museum, where the wires were supported clear of the walls on insulators of porcelain. That wiring had, without question, given the fullest satisfaction ever since it was first put up. Referring particularly to Mr. Bathurst's Paper, he found that he deprecated the use of iron pipes for wiring purposes. Yet he admitted, towards the end of his Paper, that his insulating tubes would not be efficiently protected against mechanical injury, unless they were enclosed in iron or steel coverings. There was, so far as he could see, no real difference between such iron-covered tubes and iron pipes lined with insulating material. In either case, however, it would be highly improper to dispense with the employment of well-insulated wire. Concerning the concentric system of wiring advocated by Mr. Mavor, it appeared to him that the curve which Mr. Mavor published with his Paper was misleading. He quite saw the point which he (Mr. Mavor) wished to make regarding the irregular employment of "wiremen," but failed to see that the curve illustrated it. There was one paragraph in the Paper—referring to insulation resistance, which had his full sympathy. Mr. Mavor said: "It is of much greater consequence to obtain a moderately high insulation which may be relied upon to be durable than to have, as can easily be had in a dry building, an insulation resistance of many megohms, which will disappear on the approach of a charwoman and her wash-bucket, or is at the mercy of the first loose slate or a leaky water pipe." That was, he maintained, a principle which should be enforced not only in house wiring, in the wiring of shops, &c., but also in the specifications issued for the cable networks of central electric light installations. The practice of attempting to ensure good and lasting cables by specifying very high insulation resistance defeated its own ends, because a high insulation resistance, as was well known, could be obtained by other means than by quality or by thickness of insulating material. He did not wish to suggest that evening precise terms for a satisfactory cable specification, but his own opinion was that more reliance should be placed upon kind and quality of material and upon thickness of the insulating covering increasing with voltage, than upon hundreds and thousands of megohms. It could scarcely be insisted upon too strongly that a cable having a comparatively low insulation resistance was frequently a better and a more durable cable than one having a much higher insulation resistance, and also that conversely a high insulation resistance was not a proper criterion as to the permanent quality of a cable. There was only one point more to which he wished to allude. There was no doubt in his mind that the system of concentric wiring before them that evening was to all intents and purposes a development of the single-wire system which Mr. John Raworth worked out many years ago in connection with ship lighting, where he used either the ship as return or concentric leads such as described by Mr. Mavor. The experience of the last 10 years had shown them to be thoroughly reliable and satisfactory.

Mr. A. A. C. CAMPBELL SWINTON said that with regard to Mr. Mavor's paper, he thought that some people who were connected with

Digitized by Google

the carrying out of electric wiring were of the impression that this concentric system, although very excellent from a mechanical point of view, and very suitable for warehouses and factories, was not suitable for highly decorated houses. He must confess that he was somewhat of that impression himself until recently, but a few months ago he was given an opportunity by Messrs. Mavor and Coulson to see a house in the neighbourhood of Dumbarton, where they had carried out an installation; it was an exceedingly highly decorated house, he might say over decorated, but undoubtedly this system lent itself exceedingly well to the wiring of a house, however much decorated it might be. There were certain advantages in respect to having only one wire practically, the other being insulated, which enabled them to have exceedingly small switches, and to make with great ease switches and fittings which were not unsightly. These points were of great importance where decorative effect was required. There was, however, one great difficulty with regard to the concentric system. It was impossible, in most cases, for contractors to maintain two separate staffs, two separate classes of workmen. If they were going to carry out their work in the ordinary way with wood casing, certainly if high-class work was to be done, a large portion of the staff ought to be of the house carpenter class; if, on the other hand, the work was to be done with the concentric system, they did not want carpenters at all, but something of the nature of a plumber, and men of the same experience were not quite suitable in each of the two cases. This concentric system was applicable to installations where a separate plant was used; it was also applicable where alternating currents with a separate transformer were used; but it seemed, at any rate at present, it was not applicable where the supply was taken from any ordinary continuous current system. He had at the present moment a case in point, where he was met with the difficulty that the Edinburgh Corporation were unable to sanction the use of the concentric wiring, which was otherwise highly desirable, for the reason that the Board of Trade would not allow them to have one of their conductors earthed except at the central station. If they would allow the conductor to be earthed at the feeding point it would meet the case. It appeared to him that where the concentric system was not admissible, wood casing, in the case of dry buildings, really answered very well. In the case of wires that had to be buried in wet plaster he did not think wood casings were advisable, and it appeared to him that iron pipes were worse; he was inclined to think Mr. Bathurst's tubing was an excellent arrangement for that purpose. With regard to the current that small wires would carry without danger, he had made a few experiments in this matter, and found that a No. 3/22 S.W.G. wire, the ordinary sized wire, when used for single lamps in better-class installations, insulated with vulcanised rubber and put in wood casing in the ordinary way, would carry 26 amperes; after running with 26 amperes for half-an-hour, the temperature was only raised to 107°F., and the current density was 13,700 amperes per square inch. He also tried a No. 3/25 wire for 55 minutes, and this, with 26 amperes, got to 242°F., only a little over the temperature of boiling water. He took it to the point at which the temperature did not rise any further. He was not advocating the employment of these things, but was only mentioning them, as he thought there was a great deal of nonsense talked on these points to the effect that they could not use those very high current densities because of the drop in volts. He did not recommend them; but about half those current densities he was quite sure would be absolutely safe. After current had been flowing in this wire for 55 minutes the temperature became permanent, and the current density was 28,900 amperes per square inch. He found that an ordinary flexible cord of 36/38 wire would carry 10 amperes, rising to 150 or thereabouts, quite comfortably; it never got any hotter so long as it was straight. The current density was 25,000 amperes per square inch. The fact was that with very small wires the cooling effect was so great that very high current densities were perfectly safe, but they were not advisable, because of the drop in volts.

Mr. G. S. CORLETT said, having been rather sceptical about this concentric wiring, he had used it on two or three important installations, and was agreeably surprised with one or two points in connection with it. The first was the little difficulty in training workmen to deal with the system. Secondly, the very cheap manner in which the whole job could be done. For example, a job embracing something like 600 16 c.p. lamps in a Lancashire cotton mill cost at an absolute prime cost figure, exclusive of dynamo and switchboard something like 17s. per lamp. He found that they had not the slightest trouble, that an ordinary plumber could in half an hour make a joint as well as the trained men whom they got down to show them all about it. It seemed to him that there was a great deal of unnecessary prejudice about burying their wires in casing. A great deal was said about the desirability of having their wires accessible, but a great many of them had to live in houses still fitted with gas pipes, and he never yet heard of a householder who complained of the inaccessibility of the gas pipes. As to the difficulty of nails being driven into the wire it seemed to him that with this system there would be no trouble at all from faults of that character. So far as his own experience of private installation work went, the present insurance system was little more than a farce. A representative of an insurance company recently called upon him, and something like the following conversation took place:—"I hear you have done an installation for Messrs. So-and-so." "Yes." "I want to know something about it." "What do you want to know?" "Well, I don't know, does it conform to the Phœnix rules?" "Yes, I think so." "All right, good morning! that is quite satisfactory." And the policy was endorsed. Mr. Geipel had alluded to the wickedness of central stations in shoving 200-volt lamps down people's throats. He had been using 200-volt lamps, and he had been waiting anxiously to hear in what the particular wickedness consisted. He never found the slightest trouble in keeping up the installation, and there were no more faults on the 200-volt circuit than on the 100-volt circuit.

The CHAIRMAN (Sir David Salomons) said as several other members wished to speak it would be necessary to adjourn the discussion until the next meeting, but before closing this meeting he wished to say a few words upon the subject before them. As they knew, he had personally very strong views on this question, but he need not express them now. He had always maintained and should continue to maintain that when a man purchased a horse he would not choose that animal except with special regard for the purpose to which he intended to apply it; if he wanted to run a race he would not buy a cart horse. In wiring they must choose their system with a view to the purpose to which it was to be applied, and it would be ridiculous to put down a hard and fast rule to be generally applicable. In some cases it might be perfect, in others it might be expensive and even unnecessary. Something had been said about the inspectors for the insurance companies, and he might give them an instance of an experience of his own. It was not so many years ago since electric lighting was introduced into this country, and he was probably one of the first to have it in his house. When the inspector from one of their greatest offices came down to see the fittings, and he (Sir David) made some reference to cut-outs, the inspector asked him the meaning of the word cut-out. When it was explained to him that the object was to prevent fire he was satisfied and went away. He (the speaker) did not think any inspector would be satisfied with such a brief explanation now; they had been educated, and by that Institution. The object of the Institution rules, now being revised in the most thorough manner, was not that they should be taken as examples for the world to follow, nor was it intended that no installation should be passed unless it complied with those rules, but to show what a perfect installation should be. He doubted if anyone could produce such a perfect installation, although it might be approached very nearly in the case of buildings of a very inflammable character. But they were doing a useful work in showing what could be done in exceptional circumstances. The idea which householders had that everything was right when an inspector has passed a building was quite erroneous because inspectors did not pretend to pass only those installations which were absolutely perfect. If the life insurance companies only passed those men and women who were absolutely sound it was quite clear that they would soon have to close their doors. What they had to consider was the average law of risks, and to assume that a certain number would die and a certain number would not, and that was the course which the fire insurance companies also had to pursue. The chief difficulty in connection with concentric wiring, good as it might be, in many cases, was that the householder should be a man capable of making up his mind in advance, a very difficult thing to do when he had had no large experience with other illuminants and could not foresee what alterations might afterwards be made. With regard to central station insurance he hoped very much that all engineers who had to do with central stations would join together and start some organisation which would deal in a fair way with electric lighting industry. To conclude he sincerely hoped they would be able to find a method of bringing about the good wiring without interfering with the liberty of the subject by fire office inspectors.

The discussion was adjourned until February 13th.

THE INSTITUTION OF ELECTRICAL ENGINEERS AND NATIONAL DEFENCE.

The following circular has been compiled by the Special Committee on National Defence recently appointed by the Institution of Electrical Engineers:—

The Council of the Institution of Electrical Engineers have resolved, "That steps should be taken to render available for purposes of national defence the technical skill of electrical engineers, and that a Committee be appointed with instructions to take such steps as it thinks fit to attain that end," and have appointed the following gentlemen as members of the Committee: The President (Dr. J. Hopkinson, M.A., F.R.S.), Sir Frederick Abel, Bart., K.C.B., D.C.L., F.R.S., Mr. R. E. Crompton, and Major-Gen. C. E. Webber, C.B. (Past Presidents), Mr. H. Edmunds, Mr. R. S. Erskine, and Mr. A. E. Mavor, to whom have since been added Sir Benjamin Baker, K.C.M.G., LL.D., F.R.S., and Prof. A. B. W. Kennedy, LL.D., F.R.S.

It hardly seems necessary to point out in how many ways a practical knowledge of electrical science could be made useful in time of war. Everyone knows that the acquiring of a knowledge of this science is a not unimportant part of the training of Military Engineers. This knowledge electrical engineers already possess, but they have at present no opportunity in time of peace of preparing for the practical application of that knowledge for the purposes of war.

In order to carry out their instructions, it is necessary for this Committee to ascertain what support it may expect from Members of the Institution, and others engaged in electrical industries. Hence the present communication and the following questions are addressed to you. One of the objects of this Committee is to ascertain if there are candidates amongst the electrical engineers to fill the vacancies in the list of Officers. In order to enable you to judge of the matter it may be well shortly to state the existing conditions of service in the various corps, particularly of Military Engineers, which now form part of the Reserve Forces of this country.

Digitized by Google

These are divided between militia and volunteers, and are described, with a list of the names of the commissioned officers, in the Monthly Army List, which also gives the various places where those corps are located. With one exception (the Corps of Railway Managers and Engineers) they are formed in battalions and companies, having the usual military organisation. The Volunteer Force is composed of the following arms: Light Horse, Artillery, Engineers (fortress and submarine mining), Rifles, Medical Staff Corps.

The Corps of Engineers (Submarine Mining) is perhaps the arm to which electrical knowledge is most extensively applied at the present time. There exist divisions located on the Clyde, Forth, Mersey, Severn, Tay, Tees, and Tyne. The divisions are in general highly efficient, but there is a lack of officers. The preliminary training of officers requires in all about six weeks' work, which may be spread over two years. The duties of officers include attendance in camp at the headquarters of their division for not less than eight or more than 15 days, and at 48 drills, a full day's work counting as six drills. The advantages are—very interesting and healthful work and an allowance of 10s. a day employed in training or in camp.

In the other arms there is much less need for attendance at a camp which may be remote from the home of the volunteer. The corps of Fortress Engineers is recommended to those who cannot afford time for prolonged attendance at a distance from their residence. The following is a list of the existing regiments of Fortress Engineers: 1st Middlesex, 1st Lanarkshire, Edinburgh City, 1st Lancashire, 1st Newcastle-on-Tyne, Yorkshire (West Riding), 1st (Sheffield), 2nd (Leeds), Gloucestershire 1st (Cheltenham), Cheshire 1st (Birkenhead), 2nd (Railway) Crewe, Denbigh, Tower Hamlets 2nd (East London), Cumberland, Surrey, Hampshire 1st (Portsmouth), Glamorgan, Essex, Devonshire and Somerset 1st (Exeter), London 1st (North), Flintshire 1st (Buckley), Northamptonshire 1st (Peterborough), Durham 1st (Jarrow), Aberdeenshire 1st.

In the case of the militia longer attendance is required in camp than in the case of the volunteers; for example, the militia submarine miners have annually 55 days in camp, and during the first year four months' training. Of this arm there are divisions located at Portsmouth, the Needles, Plymouth, the Thames, the Medway, Harwich, Milford Haven, Western (Severn), the Humber, and Falmouth.

Special Corps.—The modern development of the uses of electricity is certain to lead to its extended application in war time. It is proposed, therefore, subject to the approval of the War Office, to organise and train a special corps of electrical engineers, whose duties will be defined at a later date.

It will further be the object of the Committee to ascertain if the Military Authorities will regard favourably the enrolment of electrical engineers on some such basis as was followed in the case of the railway engineers, by which the services of many who cannot afford the time for organised training, but who are willing to seek certificates of efficiency suitable to their attainments, can be promptly utilised by the War Office in case of national emergency.

This statement will, we believe, enable you to judge which branch of the force you could most usefully join. Will you kindly reply to the questions put on the accompanying form? Later, if you are disposed to take an active part in the movement, you may expect to hear from us further. If you occupy a leading position, superintending the work of artizans, will you also ascertain and inform the Committee how many of these in your employment would be willing to join such a special corps as has been suggested?—On behalf of the Committee,

J. HOPKINSON (President).

1. Are you willing as an electrical engineer to register your name as ready to undergo training, and to serve in case of urgent need?
2. Are you willing to begin training at an early date, and to accept a commission in the Reserve Forces if obtainable, or to join the ranks of a volunteer corps?
3. Which branch of the Reserve Forces do you prefer?
4. Would you prefer to join a special corps of electrical engineers?
   (*a*) As an officer.
   (*b*) In the ranks.
5. Are you at present a member of any volunteer corps?

Red Glass.—Photometrists and others interested in optical research will be glad to know that the firm of Putzler Bros., of Penzig, in Germany, have succeeded in making red pot glass which is very clear and bright, but is opaque to the whole of the blue side of the spectrum, down to the line of the wave length 628. There has hitherto often been trouble in obtaining good samples of red glass for optical-testing work and for obtaining non-actinic illumination.

PROF. RÖNTGEN'S EPOCH-MAKING DISCOVERY.

In the *Zeitschrift für Elektrotechnik* of January 15th, Prof. Boltzmann states his views on Prof. Röntgen's recent discovery under the above title. In a long introduction he reviews the fundamental laws of the wave theory, sums up what has been done in this branch of investigation, and after a *précis* of Prof. Röntgen's experiments (see *The Electrician* of January 24th) he proceeds as follows:—

"The hypothetical luminiferous ether, in which all these wave-motions apparently occur, exhibits a striking analogy to the behaviour of elastic and more especially of gelatinous bodies. These latter are always capable of transmitting longitudinal as well as transverse waves. Hence it has long been suspected that longitudinal ether-waves existed, though they had not been discovered. As neither the phenomena connected with Röntgen nor with cathode rays pointed to transverse vibrations, Röntgen gave it as his opinion, with all reserve, that the waves discovered by him might be the long-sought longitudinal-ether-waves. In all elastic bodies, and especially in gelatin, the rate of propagation of longitudinal-waves is far greater than that of transverse-vibrations. If this be the case also in the luminiferous ether, Röntgen rays, notwithstanding their small period, may be of considerable wave-length. The small period of the waves would explain their fluorescence-exciting property, which apparently becomes most powerful when the vibrations take place at a speed approximating that of the molecular vibration. The great wave-length would explain the ease with which these waves, like Hertzian waves, pass through most bodies. It is to be noted in this connection that the deep tones of the music in a house next door—those, that is to say, of the greatest wave-length—pass through the party-wall much easier than do the high tones. Cathode rays, on the other hand, would seem to be longitudinal waves of extremely short wave-length, resembling Röntgen in the first respect and ultra-violet light in respect of their absorption and wave-length.

"I have already pointed out many possible utilitarian applications of Röntgen's discovery. Its greatest importance, however, consists obviously in the fact that once again we have become acquainted with a new agency. The discovery of Hertzian and of cathode waves gave rise to justifiable excitement. Nevertheless the former are not appreciably different to light waves, and the latter are bound fast within the narrow region of the Hittorf tube, and are on this account but little accessible to science and practice. Röntgen rays, however, are a completely new large-scale phenomenon.

If we remember to what discoveries the investigation of the most insignificant new natural phenomena, such as the attraction of small bodies by rubbed amber, of iron by the lodestone, the convulsive twitches of a frog's leg due to electric discharges, the influence of the electric current on the magnetic needle, electro-magnetic induction, &c., &c., has led us, one can imagine to what applications an agent will be turned which a few weeks after its discovery has given rise to such surprising results. It makes one rejoice to think that in spite of all our discoveries in natural science, the stream of wonderful phenomena still flows on undiminished, and that just within the last few years new sets of phenomena and agencies have been discovered which should afford material for research for decades to come, and the useful applications of which will be witnessed by those who live to see the coming century."

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, January 31st.

KING'S COLLEGE ENGINEERING SOCIETY.

4:15 p.m. Meeting at King's College, Strand. Presidential Address by Magnus Mowat, and a Paper on "Railways."

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Annual General Meeting at 25, Great George-street, Westminster. Paper to be read: "Notes on Steam Super-heating," by William H. Patchell.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at the St. James's Hall Restaurant (Banquet Room), Regent-street, W.

MONDAY, February 3rd.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Royal United Service Institution, Whitehall. Presidential Address by Samuel Herbert Cox.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture III.: "Alternate Current Transformers," by Dr. J. A. Fleming, F.R.S.

TUESDAY, February 4th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "Developments in Gas Engines," by Dugald Clerk.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON,

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. *[In preparation.*

THE NEW RADIATION.

Are RÖNTGEN'S rays a stream of material particles? or are they ultra-violet waves of extreme smallness? or are they a new kind of radiation altogether? These are the questions which are now being discussed in every physical laboratory in Europe, and probably also by this time in America, Australia, and Japan. A further question is likewise arising—viz., as to whether the rays are, indeed, anything in any sense new; whether they should not more properly be styled LENARD'S rays, if they are to have a name of the sort, for temporary—we hope only temporary—purposes.

How much do we know now that we did not know by the end of 1894? Apparently very little. We had then been told that rays emanated from highly exhausted vacuum tubes, that these rays excited fluorescence strongly, affected photographic plates, could pass readily through aluminium and other light substances, whether metallic or not, but were stopped by a sufficient thickness of sufficiently dense matter, whether it was ordinarily called transparent or not. Shadow photographs were taken of objects on a plate enclosed in a light-tight aluminium box, and differences of transparency were clearly exhibited. The rays were shown to proceed in straight lines, except in so far as objects placed in their path diffused them, as milk and other turbid media diffuse light. The rays were found to discharge electrified bodies upon which they fell, and thus to imitate one of the actions of very ultra-violet light. It was further known that the rays could get out of the vacuum tube not only through an aluminium window, but also, though in less quantity, through glass. On the other hand it was proved that the rays could be deflected by a magnet; and from this circumstance, chiefly, it was argued in this country that the LENARD rays were but an extension of the previously known cathode rays of HITTORF and CROOKES; that they were, in fact, electrified and radiant molecules of matter. This hypothesis was, however, vigorously contested by Dr. LENARD himself, who consistently urged that his rays were ethereal, not material, and that he had discovered a new kind of radiation, the properties of which he endeavoured

Digitized by Google

to ascertain by a laborious series of accurate and skilful experiments. These results of LENARD received respectful attention from professed physicists, and the discoverer was vainly urged to come and describe them at the Oxford meeting of the British Association, but the general public took not the slightest interest in them, nor can it be said that the information was ever effectively conveyed to the general public.

A few weeks ago, however, Prof. RÖNTGEN, of Würzburg, happening apparently to possess a CROOKES tube exhausted to the precisely required degree, observed phosphorescence of a striking kind under extraordinary favourable circumstances. Most of the phenomena observed by LENARD were rapidly and independently repeated, and one of the shadow-throwing objects employed was the human hand. Both by immediate phosphorescence and by photography the bones were found less transparent than the muscles, and straightway an application to medicine and surgery was evident, and the daily papers promptly took the matter up and blazoned the discovery abroad.

Prof. RÖNTGEN, like Prof. LENARD, argues that the effects are due to a new kind of radiation; but he further argues that his rays are altogether different in kind from LENARD rays, inasmuch as they are not deflected by a magnet. Hence arises a most interesting scientific controversy, which will lead, in all probability, to much experimenting and to rapid progress, the outcome of which it would be rash at present to attempt to predict.

Meanwhile we must congratulate Prof. RÖNTGEN on the enthusiasm and interest his discovery has aroused amongst the general public—it was the *hand* that did it. A sensational result which at first sounds like a hoax, and which in any case it is safest at first to disbelieve, that is the sort of thing in which the public delights, and for the space of nine days, more or less, will flock to lecture rooms and soirées to hear about and see. And certainly the fact that such numerous applications seem opening out before this mode of prying though visually opaque screens is one of great importance. The discovery is not now a matter of the laboratory and the study, but is one in which the whole world may well feel interested. So long as individuals of the human race continue to professionally inject bullets into one another, it is well to be provided with easy means for inspecting the position of the injected lead, and to that extent aiding the skilled operators whose business and joy it is to extract it. Not only bullets, however, but dislocations, fractures, fragments of bone, needles, and other foreign bodies can no doubt before long be thus inspected *in situ*. With the stethoscope it has been possible to listen to the workings of the interior of the human frame; with the new radiation it is to be hoped that the human frame will become, to skilled vision, something akin to transparent, and that it may become possible to practically see into it as well. Engineers are hoping to be able to detect flaws in pieces of metal by the new radiation's aid, though whether so thick and massive a piece of metal as a screw-shaft will ever be got sufficiently transparent is a question at present unanswerable. Electricians may, perhaps, inspect the interior of standard resistance coils, and observe how the wire is getting on after lapse of time, though perhaps in their case the present electrical method of testing is, after all, the best. They have long been able to spy out faults in buried cables without any kind of visual aid, but it is just conceivable that an inspection of such windings as occur on armatures and the like might sometimes give useful information. Whatever may be the precise degree of novelty attending Prof. RÖNTGEN's discovery, there can be no doubt that he has succeeded in obtaining the rays in a much more powerful and effective manner, and thus providing us with an essentially new instrument of investigation. If the explanation of the rays really lies in the direction which the discoverer himself suspects, viz., longitudinal vibrations in the ether,—vibrations which have been long speculated on but never yet observed,—the discovery will be of transcendent importance. A whole new department of Physics will lie open for investigation—not a new chapter merely, but a new treatise—an unexplored territory comparable in extent with the already partially explored domains of Light and of Heat. It is almost too good to hope that such a discovery as this can be before us, but as we write we learn that Prof. BOLTZMANN leans the weight of his authority in that direction.

DR. HOPKINSON'S PRESIDENTIAL ADDRESS TO THE INSTITUTION OF ELECTRICAL ENGINEERS.

(Concluded from page 415.)

We have supposed that galvanic effects are measured by chemical change, and that the rate of galvanic effect—or, as it is generally called, the electric current—is measured by the rate of chemical change. From a theoretical point of view it would be possible to thus measure electric currents; but for practical purposes other means are adopted—electrometers, galvanometers, electro-dynamometers, and the like. With a description of such instruments and their methods of use I have not the time to concern myself this evening. We must assume that we have the means of measuring C, the galvanic or electric current so called, at any instant, and E, the difference of potential, whether these be great or small, and with any desired accuracy.

We should now be in a position to give a detailed account of galvanic batteries and of electrolysis, and the theory of the distribution of currents in systems of conductors of any form, and we are in a position to place the theory of thermo-electricity upon a thermo-dynamic basis without the introduction of any fresh idea. These, however, I leave on one side, and hasten to consider how the phenomena of electrostatics can be based upon what we have been discussing. There is a broad group of facts very familiar to the practical electrician engaged in laying telegraphic cables of which I have as yet given no account—I refer to the phenomena of capacity. Let us examine a little more closely the statement that I made that if a slip of paraffined paper were interposed between the two parts of a conductor no electrical action would occur. Suppose that, instead of paraffined paper interposed between the ends of a wire we have a very large number of sheets of tinfoil separated from each other by paraffined paper in such wise that we have a great area of tinfoil connected together, and separated from another great area of tinfoil by nothing more than the paraffined paper. If now these two areas of tinfoil are suddenly connected to the poles of a galvanic battery we find that it is by no means true that no galvanic effect will ensue; we find that a galvanic current exists, but that, whilst it begins with a large quantity, this quantity goes on diminishing until, barring the slight imperfection of insulation of the paraffined paper, it becomes *nil*. We find, then, that it is not true to state that paraffined paper cannot form a part of a galvanic circuit; it can form a part of a galvanic circuit, but it does so under completely different laws to the metallic conductor. With the metallic conductor the difference of potential at its two ends depends only on the current which then exists in that conductor, and not at all upon the currents which have previously existed; with paraffined paper, on the other hand, the difference of potential between the sheets of tinfoil depends not at all upon the then current, but entirely upon the currents which have existed since its two coatings were connected together, and the times for which they have existed. A galvanic current may be measured by the rate of electrolysis; being measured by a rate, its time integral will have a perfectly definite meaning, and will be measured by the total quantity of substance which would be decomposed in a voltameter in the circuit. We find that the difference of potential

Digitized by Google

between the two coatings of the paraffin condenser is proportional to the time integral of the current since the time at which the coatings were connected together last. The constant ratio of this time integral of current to the difference of potential is called the "capacity" of the condenser. Suppose now that the condenser has been connected to a galvanic battery and the time integral of the current has been measured; let now the coatings of the condenser be disconnected from the battery and be connected together through any instrument for measuring the time integral of current: if this is accomplished with sufficient rapidity for loss by imperfect insulation to be negligible, we find that the time integral in the second case is equal and opposite to that which it was in the first. Here, again, is a difference from conduction in the ordinary sense. If a conductor in which a current has existed be disconnected from the source of current and be connected to any measuring instrument, no return current will be observed. Here, then, we have a new order of facts presented in an extreme case, but in fact, applicable to all kinds of insulators. Suppose we diminish the area of surface of the paraffined paper, we diminish *pro rata* the capacity of the condenser; but even when the paraffined paper is merely interposed between the ends of two copper wires it still will be a condenser having a definite capacity. There is no need to use paraffined paper to form a condenser. Two metallic plates may be insulated and placed parallel to each other; if they be connected one to one pole of a battery, the other to the other, a current will exist for a finite time; if they are now disconnected from the battery and connected to each other through a suitable instrument for measuring the time integral of current, a return current exists for a finite time. Consider now a condenser consisting of two parallel plates of very large area placed near to each other; its capacity varies as the area of the plates, and it also varies inversely as the distance between them—laws precisely analogous to those of conductors. It also, as might be expected, depends upon the material interposed between the two plates. Since the capacity of the condenser varies as the area, and inversely as the distance, whatever be the substance between the plates, there is a constant for every substance analogous to the specific conductivity of the material; this constant is called the "specific inductive capacity" of the material.

That the magnetic effects of the transient galvanic currents in insulators are the same as of corresponding currents in conductors, is a fundamental law at the basis of Maxwell's theory of electro-magnetism; it was, I believe, first definitely propounded by Maxwell, and it is one over which some of the most eminent minds have since contended. You will notice how, if the subject be arranged in the unhistorical, but not unnatural, way I have adopted this evening, this law drops so easily into its place, that its assumption would be almost unnoticed. Why should we assume that the magnetic effects of electric currents in insulators and in conductors are different? By far the most natural assumption is that they are the same.

Maxwell's electromagnetic theory of light—one of the great generalisations of the century—is directly based upon this law. What is this theory? It is simple enough in its character, broadly stated. Suppose you have an electrical disturbance, a transient galvanic current, in any dielectric, this disturbance—assuming the magnetic effects of currents in dielectrics to be the same as in conductors—will be propagated as a wave in directions perpendicular to the direction of the currents. The velocity of the wave can be calculated from purely electrical experimental knowledge; it is 3×10^{10}, if the dielectric be a vacuum. The velocity of light is 3×10^{10}. We know nothing of what light is; we do know that it is a wave, and that the disturbance is perpendicular to the direction of transmission of the light; but what is the ultimate nature of that disturbance we have no idea from the standpoint of the science of light. Is it not infinitely probable that the waves of light are none other than the electrical waves which we know must exist, and must be propagated with the observed velocity of light? And, mark, this theory demands no ether; it merely identifies the phenomenon of light with known phenomena of electricity and magnetism; it demands no knowledge of the fundamental nature of these phenomena, it demands only a knowledge of their laws. Surely Maxwell's generalisation is similar both in kind and in magnitude with the discovery of universal gravitation. Newton showed that the force which caused any body—an apple, if you like—to fall on our earth was the same as the force which kept the planets in their courses. He gave no theory of how that force was transmitted, nor of what, in its inmost nature, it was. He merely identified the two forces as one. So now Maxwell's theory may be shorn of all reference to an ether; it identifies as one the forces whereby light is transmitted and the forces with which we are familiar in our dynamo machines, and shows that they are measurably the same. It does not pretend to say what electricity and magnetism are, or what, if any, is the medium whereby the disturbances on which both depend are transmitted. Whether the postulate of an all-pervading ether be, or be not, a metaphysical necessity, surely it is well for the practical man and the physicist to leave the question to the metaphysician. My point, however, is that the hypothesis of two electric fluids and the ethereal theory of light have rather delayed than accelerated the acceptance of a great generalisation. Let us now return to elementary matters.

I have just stated that the capacity of two large plates near and parallel to each other varies as their area, and inversely as their distance. In what units are we to measure capacity? If we have already chosen a unit of resistance, a unit of capacity must follow from that through the units of potential and current. It would be the capacity of that condenser which, if brought to unit difference of potential, would discharge a galvanic current whose time integral was unit current for unit time. It would be quite natural to define as a unit of resistance the resistance between opposite faces of a cube of a defined substance at a defined temperature, in which case the dimensions of resistance would be the reciprocal of a length. Or, again, we might lay by a piece of wire and carefully preserve it, and say, let that be our unit of resistance. Then resistance would have no dimensions in terms of mass, length and time—it would be a fundamental unit. In either case we should introduce physical constants into our formulæ for electrostatic and electromagnetic phenomena, depending in the one case on the physical properties of the substance chosen, in the other on its actual dimensions. If the history of electrical discovery had followed the course adopted in this discourse, and it had become necessary to fix upon a unit of capacity at the point we have now reached, it would have been very natural to have taken the capacity per square centimetre of two plates at unit distance, the insulating medium being vacuum. We shall see shortly what is the actual electrostatic unit which has been chosen, but the fact is there is nothing specially natural, nothing specially absolute in the choice.

It is a matter of very great interest to know the capacities of condensers of various forms. Let us take, for example, the case of a sphere enclosed concentrically within another sphere. If r_1, r_2, be the radii of the two spheres, the result is that the capacity varies as $\frac{r_1 r_2}{r_2 - r_1}$; if r_2 be very great in comparison with r_1, the capacity varies as r_1. The electrostatic unit of capacity ordinarily adopted as absolute is the capacity of a sphere of unit radius enclosed concentrically in a very great sphere, with vacuum as insulator. From this, remembering that the product of a difference of potential and a galvanic current shall be power in ordinary mechanical units, all other units will follow. Thus time integral of current divided by difference of potential or capacity is a line; therefore conductivity is a velocity, and resistance the reciprocal of a velocity. Difference of potential multiplied by current is power, and has dimensions $M L^2/T^3$, but potential divided by current has dimensions T/L; therefore current squared has dimensions $M L^3/T^4$, and current $M^{\frac{1}{2}} L^{\frac{3}{2}}/T^3$, and so on.

Again, the capacity of two plates, area A, distance x, can be deduced from that of two concentric spheres at a small distance apart: it is $A/4\pi x$ in these units.

We may now prove that mechanical forces must exist between the plates of a charged condenser. Let a condenser be formed of two parallel plates of area A at a distance of x from each other, the distance x being capable of variation; let the condenser be charged to a given difference of potential and then insulated, and the position of the plates in relation to each other varied. If the condenser be then discharged, it is found, first of all, that

Digitized by Google

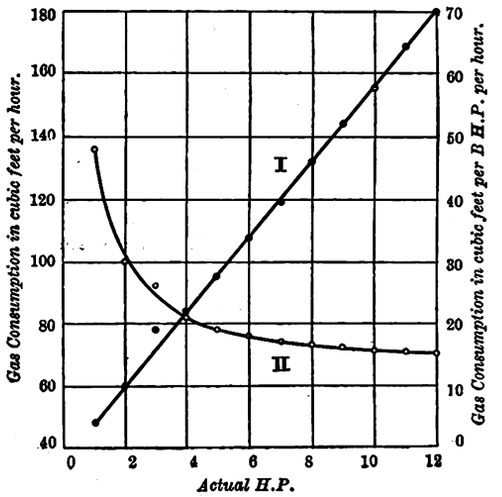
the total discharge is the same, however the position of the plates be varied. Suppose now that the condenser be charged to a difference of potential E, and a quantity, or time integral, of current Q, the work done in so charging the condenser will be $\frac{1}{2}$ E Q. Let now the condenser be insulated, and the distance of the plates increased to $x+\delta x$: the capacity of the condenser will be diminished in the ratio $x/(x+\delta x)$; and therefore, since the quantity remains the same, the difference of potential will have increased to $E(x+\delta x)/x$. Now discharge the condenser. The work done by the discharge will be $\frac{1}{2} E Q (x+\delta x)/x$, or an amount of work $\frac{1}{2} E Q \delta x/x$ greater than was done in charging the condenser. This work must come from somewhere. The only way in which it can be introduced is by the work done in separating the plates from each other. To increase the distance between the two plates by an amount δx therefore requires that we shall do mechanical work $\frac{1}{2} E Q \delta x/x$ upon the plates. This mechanical work is done through a distance δx, therefore a force must be exerted in separating equal to $\frac{1}{2} E Q/x$; hence it follows, as a matter of necessary consequence from the laws of the capacity of conducting surfaces in the presence of each other, that those surfaces shall when charged act mechanically upon each other; and the amount of mechanical force is determined.

Now $E \cdot \frac{A}{4\pi x}$ is equal to Q, hence the force between the plates is $2x\frac{Q^2}{A}$. Let us now suppose that matter is laid upon each plate of density $\frac{Q}{A}$, and that the matter on one plate attracts that on the other plate with a force varying as the inverse square of the distance: the resultant attractive force between the plates is exactly $\frac{2\pi Q^2}{A}$; hence we should accurately express the facts of attraction of two plates if we said there is on each plate a charge of electric substance, and every particle of substance on the one plate attracts every particle on the other with a force varying inversely as the square of the distance. But that the facts can be so expressed is no evidence that any such electric substance exists.

I do not propose to touch on electromagnetic and magnetic phenomena; I would only point out this: Just as electrostatics has been based on action at a distance between hypothetical electric fluids, so magnetism has been based on the action at a distance of hypothetical magnetic fluids. There can be no doubt that the science could be easily rearranged, and that the phenomena of electro-magnetism could be made fundamental, and that the facts concerning permanent magnets could be made subsidiary thereto, exactly as we have deduced this evening the facts of electric attraction from the phenomena of current-electricity. I believe that in the future this is the way the science must be arranged for practical men. They are but little concerned with the attractions between charged spheres and the like, and very much concerned with the laws of currents and differences of potential and capacities. The theory of permanent magnets has for the modern electrical engineer only a general interest, but the laws of magnetic circuits and induction therein are all-important. It would seem that the subject needs rearranging, and that that which is most important should be put most prominently forward. I even venture to think that this would be no loss to pure science; we should see with increased clearness how little we know what electrical phenomena really are, and how much we know of how electrical laws work. We should see how much there is that is arbitrary and conventional, and by no means absolute, in the system of units we have adopted. The science of electricity is so essential to the practical electrical engineer that it should be arranged so that he can learn in logical order what he most wants to know. In what I have briefly indicated, there will be something which is trite to all, and something, perhaps, not easy to comprehend when stated too shortly. My aim has been rather to excite in your minds discontent with the way in which the science of electricity is usually arranged, in the hope that such discontent may take an articulate form and become a demand for something more convenient for your particular purpose. When the demand becomes clear, it will not be long before it is supplied.

THE ECONOMY OF GAS ENGINES.

The accompanying table and the diagrams plotted from it are based upon particulars of a series of gas engine trials, which were published by Mr. Nelson W. Perry in a Paper on "The Storage Battery or the Gas Engine as an Auxiliary," read before the American Institute of Electrical Engineers. The interest in the trials lies mainly in the fact that they furnish a complete account of the consumption of a small gas motor for all loads below that at which it was rated. Unfortunately, the type of engine is not stated in the Paper, nor the manner of reducing the consumption at reduced loads. In the diagram, Curve I. shows the total consumption of the engine, in cubic



feet of gas per hour, and Curve II. gives the gas consumption in cubic feet per brake horse-power per hour. The observed results are shown by the circles on the curves. It will be seen that the results are somewhat below the rates of consumption which would be obtained in ordinary practice, but the general types of the curves are probably not altered on that account.

THE ELECTRIC LIGHTING OF MELBOURNE.

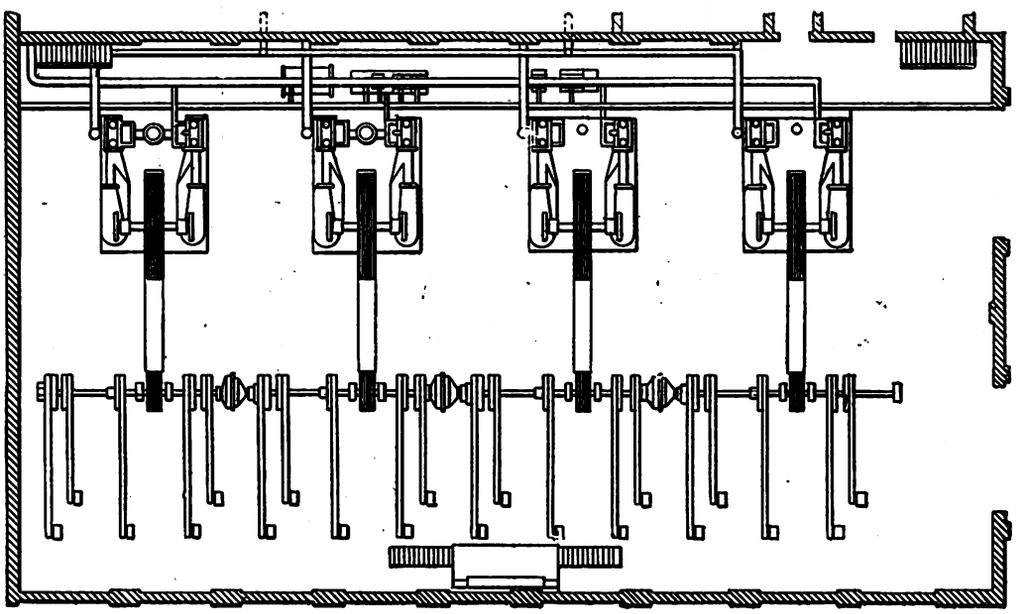
To the September, 1895, number of the *Cosmos Magazine*, an Australian literary journal, Mrs. Charles Bright contributes an interesting little article on "The Electric Lighting of Cities," in which she has taken the lighting of Melbourne as a text upon which to express her advocacy of municipal control of such matters. Incidentally, we learn a good deal of the peculiarities of electric-lighting systems at the Antipodes, and it is interesting to contrast these with our boreal methods. We are assured that, so far as the southern hemisphere is concerned, Melbourne has led the way; and it must be gratifying to the ratepayers of the Victorian capital to hear that the balance sheet shows that they "have not only a light of six times the power of the superseded gas, but at this early stage, with an assured saving of almost £1,000 a year over the

Digitized by Google

former gas bill." This success should be all the more gratifying from the fact that it is obtained with a type of station which every central-station engineer in this country would characterise without hesitation as antiquated; and we may point out that, however less costly than gas the Melbourne station may be, by comparison with the modern type of English station it cannot but be sadly inefficient. To make this point clear, we will turn for a more detailed description of the station to a Paper read by Mr. A. J. Arnot, the electrical engineer to the Melbourne City Council, before the Victorian Institute of Engineers, in 1894. The accompanying plan of the machinery room will also enable an idea of the Melbourne system to be obtained. The following is an abstract of Mr. Arnot's description :—

"The buildings consist of an engine and dynamo room, 138ft. by 78ft., boiler house and stokehole 84ft. by 37ft., coal bunkers, testing room, stores, offices, fitters' shop, and apartments for resident engineer. The system adopted for lighting the streets of Melbourne is known as the continuous-current series arc and incandescent, favourably known and well tried in America and in some parts of Great Britain. The streets to be lit are those within the city limits, which embrace an area of 4,700 acres. Arc lamps of 1,200 nominal candle-power are used in the main thoroughfares, while incandescent lamps of 20, 25, and 32 c.p. are erected in the lanes. The generating station is situated at a point nearly equi-distant from the two main extremities of the city. The site is high enough to be well out of the reach of floods, and at the same time not too far from the river Yarra to prevent its water being used for condensing purposes, and is also conveniently situated to wharf and railway for the delivery of coal. A plan of the generating station is attached, of which the following particulars may be interesting: The plant is laid out in four sections, each complete in itself. Three of these are sufficient to light the whole of the city, the fourth being at all times a stand-by in the event of any part of one section failing. A section consists of one 250 H.P. boiler, one 300 I.H.P. engine, one 30ft. length of shafting, five 50-light arc dynamos, and one 2,000 8 c.p. incandescent lamp dynamo (this last to be erected). The boilers consist of four water-tube, Babcock and Wilcox manufacture. The heating surface of each boiler is 2,823 sq. ft., and the grate surface 51 sq. ft. These boilers are now so generally and favourably known amongst engineers, that a description of them from my pen would be out of place. They are fed by steam pumps of the direct-acting duplex type two in all, each of 3,000 gallons per hour capacity; one pump being, therefore, sufficient to feed three boilers. There are two independent delivery pipes, each boiler being connected to both of them, and the connections to pumps are so arranged that by a manipulation of valves either pump may be connected to either delivery pipe. The suction pipe may be fed from three distinct sources: 1st, hot well; 2nd, storage tank of Yan Yean water, capacity 48,000 gallons, situated under the coal bunkers; 3rd, from Yan Yean direct. The feed water is forced through an economiser situated in the flue, having a total heating surface of 3,750 sq. ft., or may if necessary be forced direct to the boilers. The economiser is divided into two parts, so that either half or whole may be used. Before the flue gases enter economiser, and after they leave same, the temperature is recorded by pyrometers. A draught gauge is fixed in the flue, as is also a test-tube connection for sampling the gases. On the feed-water pipes on either side of the economiser thermometers are attached. The main steam pipe is on the principle of the ring of steel, 10in. and 8in. diameter, cast-iron flanges, copper bends and expansion pieces. Branching into the main pipe on the boiler side are four supply pipes, and on the other or engine side are four connections to high-pressure cylinders. Each branch has its own valve. The ring has two valves between the supply-steam and delivery-steam connections, for use in the event of a part of the steam-pipe service becoming unusable. The exhaust main, which consists of a 12in. cast-iron pipe, runs the whole length of the building under the floor, as shown by sectional drawing. Branching into it are the exhaust pipes from the four engines. This exhaust main is connected by valves to two surface condensers, each capable of condensing the steam of three engines. The main exhaust is also led into the smoke stack, when by the opening of a valve, should necessity arise, the steam may exhaust into the atmosphere. The condensers are situated below the engine-room floor. Alongside each condenser is a separate circulating and air pump. The circulating pumps take their supply from two large tanks underneath the dynamo room, each tank being capable of holding 125,000 gallons of water. This water is pumped up from the River Yarra by a compound duplex direct-acting pump of 50,000 gallons per hour capacity. The pump is situated in the Corporation Fish Markets, taking steam from the refrigerating plant boilers, and is attended to by the engine driver in charge of that plant. The distance from the lighting station to Fish Market is 900 yards, and the difference in elevation of low-water mark and level of tank is 39ft. The depth of water in storage tanks is indicated by floats connected to electric alarms, which ring when tank is full or contains only 2ft. of water. The overflow from surface condensers is into the main drain, which to the station is gas tight, as are also the walls of storage tanks. The storage tanks are ventilated by pipes in outer wall of building. The air pumps deliver into a hot well situated over the flues. The engines, which are four in number, are of the horizontal compound surface condensing type, fitted with the Rowland and Richardson's patent trip valve gear. The high-pressure cylinder is 15in., and low pressure 26½in. diameter, the stroke being 3ft., and the number of revolutions 12 per minute. The flywheel is 14ft. in diameter. Each engine drives on to its own section of 6in. shafting by seven 6¼in. ropes. The receiving pulley on shaft is 5ft. 7in. in diameter. Between each section of shafting is a patent friction and claw clutch combined, so that, should occasion arise, any engine may drive any section of shafting. There are at present ten dynamo pulleys on each set of shafting, five being fast and five loose. These pulleys are 5ft. 7in. diameter with 8in. face. Double leather belts 7in. wide are used to drive the arc machines. On each section of shafting space is left for 100 H.P. high-tension alternating-current dynamo, for which tenders are now about to be called. These alternators will be sufficient for the present demand for light, and it is proposed, with an increased demand, to extend the building for alternating plant, and then erect engines and alternators coupled direct for incandescent lighting, and the spare 400 H.P. on the arc-light plant could be used for further extensions or increased lighting in the streets, when the cost of maintenance will permit of it. The arc dynamos are of the well-known Thomson-Houston type, of 50 arc light, or 250 20 c.p. series incandescent. The armature is of the new type lately introduced by the manufacturers known as the sectional coil armature, and is a great improvement on the old style of spherical armature. There are 30 coils on each armature, 10 being coupled together in series. The dynamos, 20 in all, were bedded on top of the large storage tanks used for condensing purposes. The roof of these tanks consists of 4½in. brick arches, with a layer of concrete varying in thickness from 4in. to 18in. The cables from the dynamos are led beneath the flooring in 'compo' pipes, which are filled in with bituminous compound, to the controllers on the wall opposite each dynamo, and from these controllers along the wall to the switchboard. The switchboard is at an elevation of 8ft. from the floor, access to which is by a two-way staircase.

"As is too well known, the overhead system of conducting the cables has been adopted throughout. The great cost of undergrounding the whole of the reticulation was prohibitive, although in the near future I look forward to the placing of both the electric light leads and telephone wires underground in the principal streets. The poles used for the carrying of



Melbourne Electric Supply Station.—Plan of Machinery Room. Scale, 1in. = 24ft.

Digitized by Google

the cables are all of box or red iron bark of two sizes, 30ft. and 35ft. long. The 30ft. poles are fixed five arms in some cases, and two in others, the 35ft. poles having generally seven arms, with the exception of a few close to the lighting station, which have nine and ten. The maximum distance between the poles is 53 yards. The spanning of the streets by steel cable and suspending the lamp in the centre was objected to by the Electric Light Committee as unsightly, the erection of wrought-iron girder work as too costly, and the use of extension brackets as undesirable, owing to the necessity, if that system were adopted, of placing all the lights on one side of the street to prevent contact with the telephone wires. The system adopted was the only one left that was possible—viz., the placing of the arc lamps on top of lighting pillars on alternate sides of the street.

"The incandescent lamps are of the Sawyer-Mann type, taking in all cases the arc current of 6·8 amperes. They are so constructed that, should the filament break, the current may pass on by either the fusing together of the platinum wire of the lamp, or the burning through of a thin piece of paper inserted between the two poles of the lamp within the socket. The height from the ground of the incandescent lamp is 14ft. Some circuits in the city have as many as 120 32 c.p. incandescent lamps and 10 arc lamps in series."

Here we have a station which, whatever its striking merits, consists of no less than 20 dynamos driven by four steam-engines, not merely by belts and ropes, but also with intermediate counter shafting. We hope this is not a fair sample of antipodean supply stations; indeed, we are sure it cannot be, for the colonies are as well aware as engineers in this country of the enormous reduction in efficiency which such a primitive system must inevitably involve, not to mention the equally enormous increase in the cost of labour and repairs. We can only hope that the Melbourne authorities will apply the annual surplus of £1,000 to a scheme for promptly replacing their present antiquated plant by machinery of an efficient modern type. "The Melbourne City Councillors," we are told, "have erected an electric lighting station of so complete and extensive a character that there is nothing like it, so experts say, in the Southern Hemisphere." Perhaps the Southern Hemisphere ought to be very glad.

NOTE ON THE MEMOIR OF HERR JAUMANN, ENTITLED "LONGITUDINAL LIGHT."*

BY H. POINCARÉ.

Herr Jaumann has recently published in the *Proceedings* of the Vienna Academy† a work full of ingenious ideas, in which he attributes cathode rays to longitudinal vibrations in the ether. The experimental foundation of his theory has given rise to a polemical discussion, in which I do not wish to take part. I only desire to make some remarks on the subject of his calculations and the consequences he thinks can be deduced from them. Herr Jaumann assumes that in rarefied gases the dielectric power ε is variable, and he thus arrives at the following equations, representing the electric oscillations in such a medium, and which I reprint in Hertz notation :—

$$A\left[\varepsilon_0\frac{dX}{dt}+X_0\frac{d\varepsilon}{dt}\right]=\frac{dM}{dz}-\frac{dN}{dy},$$

$$A\left[\varepsilon_0\frac{dY}{dt}+Y_0\frac{d\varepsilon}{dt}\right]=\frac{dN}{dx}-\frac{dL}{dz},$$

$$A\left[\varepsilon_0\frac{dZ}{dt}+Z_0\frac{d\varepsilon}{dt}\right]=\frac{dL}{dy}-\frac{dM}{dx}.$$

A is the reciprocal of the speed of light, X Y Z and L M N the components of the electric and magnetic forces; ε is the dielectric coefficient, ε_0 the mean value of this coefficient; X_0 Y_0 Z_0 the mean values of X Y Z; dX/dt is very small compared with X_0 and $d\varepsilon/dt$ with respect to ε_0. The variations of ε are given by the equation :

$$k\frac{d\varepsilon}{dt}=\frac{d\varepsilon_0 X}{dx}+\frac{d\varepsilon_0 Y}{dg}+\frac{d\varepsilon_0 Z}{dz}=0,$$

where k is a constant.

The equations then become :

$$A\left[\frac{d\varepsilon_0 X}{dt}+\frac{X_0\theta}{k}\right]=\frac{d}{dz}-\frac{dN}{dy},$$

$$A\left[\frac{d\varepsilon_0 Y}{dt}+\frac{Y_0\theta}{k}\right]=\frac{dN}{dx}-\frac{dL}{dz},$$

$$A\left[\frac{d\varepsilon_0 Z}{dt}+\frac{Z_0\theta}{k}\right]=\frac{dL}{dy}-\frac{dM}{dx}.$$

If we differentiate the first with regard to x, the second with regard to y, and the third with regard to z, and add, noting that

$$\frac{d\theta}{dt}=\frac{d}{dx}\frac{d\varepsilon_0 X}{dt}+\frac{d}{dy}\frac{d\varepsilon_0 Y}{dt}+\frac{d}{dz}\frac{d\varepsilon_0 Z}{dt},$$

we get

$$A\left[\frac{d\theta}{dt}+\frac{1}{k}\left(\frac{dX_0\theta}{dx}+\frac{dY_0\theta}{dy}+\frac{dZ_0\theta}{dz}\right)\right]=0.$$

This equation shows that cathode rays, instead of being propagated in straight lines, should follow the lines of force. On the other hand, they would not be deflected by a magnetic. Herr Jaumann has indeed shown that the direction of the plane of the wave should be deflected by a magnet; but it would not be the same with the direction of the ray. In any case, therefore, Herr Jaumann must modify his hypotheses if he wishes to take all the facts into account.

CORRESPONDENCE.

THE BERRENBERG VACUUM PUMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the note in your Editorial columns for January 26, 1896, you asked the question how far a first-rate vacuum was necessary for commercial glow lamps. Well, as a filament glowing in the open air takes 31 watts per candle, one enclosd in a chamber from which 90 per cent. of the air had been pumped out, takes 15 watts per candle, and when the pressure has been reduced to about $\frac{1}{100000}$th of an atmosphere it only takes 4 watts per candle, it appears obvious that increasing the vacuum increases the efficiency of the glow lamp, and thus reduces the cost for power during the whole of its life. This is so far recognised that it is usual for manufacturers of 16-c.p. lamps to expend 15 per cent. of the cost of construction in producing the vacuum, while in the case of 50, 100 and 300 c.p. lamps the cost of pumping is as much as 50 per cent. of the total cost of manufacture. Of this I am certain. I have been engaged for years in exhausting lamps on a commercial scale with various kinds of mercury pumps.

Only one, therefore, who is quite unfamiliar with the details of glow-lamp construction could have written the following sentence in your "Editorial Note": "If a philanthropic inventor came round and exhausted lamps for nothing it would make little or no perceptible difference in the price of the lamps."

Prof. Ayrton is quite familiar with the difficulties of using the McLeod gauge, and that is why in his report the readings of the McLeod gauge are translated into "Approximate pressures in atmospheres." He is also well aware that opening a lamp bulb under mercury only gives a rough idea of the goodness of the vacuum in the lamp, but he feels certain, from the precaution he took in making the tests, "that the combination of pumps, as erected at No. 4, Huggin-lane, is capable, in 15min., in creating a vacuum as *good* as that in the best, and *much better* than that in the worst, of the glow lamps he examined; and that it is capable, in 20min., of creating a vacuum *much better* than that in *any* of the lamps he had broken under mercury."

What other means of testing vacua do we possess? The spark test is but a very rough one at the best, and cannot be applied to lamps exhausted by different methods, as the residual gases are of different natures, and therefore give different colours to the sparks. Another test is the coolness of the globe while in use; well, lamps exhausted on my Metallic Vacuum Pump are much cooler than those exhausted by mercury pumps.

Perhaps, however, the writer of the note in *The Electrician* will indicate exactly how *he* would test the vacuum in a commercial glow lamp and compare it with the vacuum in another lamp.

The writer's statement that "metal is impervious to air" is also quite contrary to my experience, for I have found that all metals, even hammered steel, allow air to pass through them. Therefore, an oil jacket throughout the whole system is absolutely necessary if a high vacuum is to be produced and maintained in metallic pipes.

With reference to the suggestion on the part of the writer that the pump is not novel, I am satisfied to abide by the

Digitized by Google

independent reports of Mr. Fletcher Moulton, Q.C., and Prof. Ayrton.

For the last sentence I must give *The Electrician* credit. It says: "To exhaust lamps well is far more important than to do them cheaply." But I have shown by four years' actual working that with the aid of my pumps incandescent lamps can be exhausted *both* well and cheaply.—Yours, &c.,

ADOLPH BERRENBERG.

[Mr. Berrenberg quite fairly asks us to state how we should make comparative tests of very high vacua, since we cannot put our trust either in the McLeod gauge method or the air-bubble method. Had we known of a really reliable method, we should have given Mr. Berrenberg the benefit of our knowledge last week. The point is that, as lamp-makers well know, the high vacua given by the McLeod gauge are as often as not more apparent than real, and cannot, therefore, be brought forward as irrefragable evidence of the vacuum-creating power of one pump as compared with that of another.—ED. *E.*].

LEGAL INTELLIGENCE.

Hall v. Alabaster and Co.

This was an action brought in the High Court before the Lord Chief Justice on Monday last, by Mr. Henry Cuthbert Hall, electrical engineer, against Messrs. H. Alabaster, Gatehouse and Co., to recover damages for an alleged libel in the *Electrical Review* (of which they are the proprietors and publishers) on April 26th, 1895, in an article headed "Storage Battery Testing Extraordinary," which discussed a report by the plaintiff upon a certain type of storage battery.

The plaintiff alleged that the defendants meant and intended to convey by the article referred to that he was ignorant and incompetent as an electrical engineer, and that he was not capable of testing a storage battery, or of making a reliable report thereon; that he was not an expert electrical engineer, and that his report was not made honestly, but contained untrue, reckless and misleading statements, made by him with a view to persuading persons to take up the manufacture to which the same related, and with the object of disparaging the manufacture of a rival invention.

The defendants, by their defence, while admitting the printing and publishing of the words complained of, denied the plaintiff's contentions. They also alleged that the words complained of, in so far as they consisted of matters of opinion, were fair and *bonâ fide* comments upon matters of public interest which did not exceed the limits of fair criticism, and which were printed and published *bonâ fide* and without malice. They also further pleaded that, in so far as the words complained of consisted of matters of fact, they were true in substance and in fact.

Mr. Lawson Walton, Q.C., M.P., Mr. Scott Fox, and Mr. Oppé appeared as counsel for the plaintiff; while Mr. H. H. Asquith, Q.C., M.P., and Mr. Eldon Bankes represented the defendants.

Mr. LAWSON WALTON, Q.C., in opening the case, said that the plaintiff was an electrical engineer, and the defendants published the *Electrical Review*, and the plaintiff by his action sought to recover compensation against the defendants for a publication which reflected both on his professional conduct and upon his professional integrity. The issues sought to be raised were (1) whether the criticism to which the defendants had subjected the plaintiff was fair, and (2) whether the statements on which they founded the criticism were true in relation to the plaintiff's action and in relation to the experiments which he described. Mr. Cuthbert Hall was a young man who had been for some years qualified as an electrical engineer. He had given considerable attention to electrical storage, and he had pursued his researches with such success as to obtain some degree of eminence in his profession. He was one of the arbitrators attached to the London Chamber of Commerce in connection with the electrical department, the editor of an electrical trade journal, and he had acquired a professional connection which was to him the source of a professional income on the continuance of which his commercial prosperity depended. In 1894 Mr. Hall was invited by Mr. Higgs to conduct certain tests of a new storage battery which Mr. Higgs was interested in, and he undertook to investigate the scientific claims and merits of this battery, which he would call the International Electrical Storage Battery. For that purpose he was furnished with I.E.S. batteries and had placed at his disposal the works of the I.E.S. Company. These experiments lasted for a considerable time, and while they were in progress Mr. Higgs was furnished with the results. After some little time Mr. Higgs suggested and Mr. Hall accepted the suggestion that the battery of the Electrical Power Storage Company, known as the "E.P.S." battery, should form the standard of comparison. That was convenient and fair; convenient because the E.P.S. battery was known to every engineer, and fair because the capacities and various powers of the E.P.S. batteries were all published in the catalogues of the E.P.S. Company, and, therefore, ready to the hand of anyone familiar with the subject. It became necessary to tabulate the results obtained, and Mr. Hall having arrived at certain figures, at the request of Mr. Higgs embodied the results of his experiments in a letter, or report, which he sent to that gentleman. The learned counsel read the report, and went on to say that it was given to Mr. Higgs, and was not a public report. How it got into the hands of the defendants Mr. Hall could only speculate. Mr. Higgs had it and said he sent copies to a few friends of his. By some means the defendants got hold of this memo., and having got it, they thought it afforded an opportunity for smart writing at the expense of the youthful engineer who had made these experiments. It was a communication intended to be read by and guide the action of certain gentlemen who had engaged Mr. Hall, and who had themselves seen the way these tests were being carried out. The defendants having got hold of this report, proceeded to indulge in a little smart and slashing writing, in which Mr. Hall's reputation as a man of honour and a scientific man were scarified, as would be seen from the libel. The learned counsel then read the libel, and contended that it suggested that Mr. Hall did not possess the most ordinary capacity for conducting a professional investigation; that he was reckless and unskilful; that his results were worthless, and that the mode in which he stated them would damn any invention, and that he had unscrupulously allowed himself to be the tool of a man who was seeking to foist on the public a worthless invention.

The PLAINTIFF, examined by Mr. Lawson Walton, said that he was a consulting engineer in connection with electricity and electrical appliances; an associate of the Institution of Electrical Engineers and editor of *Electrical Industries*, and one of the arbitrators in the London Chamber of Commerce in the Electrical Section. Although he had only been in practice since 1892 as a consulting engineer, his experience dated from 1886. He had paid considerable attention to storage batteries. In 1894 he had a conversation with Mr. Higgs with reference to a battery in which he was interested, and Mr. Higgs made various statements to him with regard to its capacity and the fall of electrical pressure. He thought it very improbable that the cell had the capacity which Mr. Higgs stated it to have, and upon his telling Mr. Higgs his opinion the latter told him that he would send cells for him to test. In May, 1894, Mr. Higgs sent him two cells to test. After he had made a preliminary test, in May, 1894, and finding that the cell had very extraordinary capacity, it was arranged that he should make a series of elaborate tests, and the tests so made should be made the subject of a Paper which he proposed to read at the Institution of Electrical Engineers. His remuneration was to be 25 guineas. Having made these arrangements 11 cells were provided for him at the works of the I.E.S. Company, at Euston-buildings, London, N.W. That was about the beginning of November, 1894. The 11 cells were all arranged in series, each cell having three plates in all, one positive and two negative. Before he began he found that the cells were in working order. He began with low rates, and charged and discharged at those low rates some considerable time, and then the rate was raised step by step. The result was that the cell bore the high rate. He kept notes of the tests, and Mr. Higgs was shown some of the curves from time to time. Mr. Higgs then wished a comparison made with some existing battery in the trade. The battery he took was the "L" type of battery referred to in the catalogue issued by the E.P.S. Company, which was the most favourable in the point of high rate of discharge and high capacity combined. In response to Mr. Higgs' wish he made out figures showing the results of the work of the new battery as compared with the published capacity of the old battery. In comparing these two batteries he did not consider that it was an essential or important feature to give the absolute size of the old battery with which the comparison was made. He furnished Mr. Higgs with the results of his tests in a letter which he wrote to him on March 21, 1895. For the purpose of comparison he reduced the areas of the I.E.S. cells to square inches, and the areas of the E.P.S. cells to square inches, and having done so, he compared the rate per square inch of the one with the rate per square inch of the other. He considered that perfectly intelligible and perfectly fair. There was no ground for the suggestion that the I.E.S. cells suffered injury at the high rates. The discharge showing the result was not an isolated experience. The discharge was repeated over and over again until the same conditions were reproduced. After that he felt justified in saying that the cell had a certain capacity at those rates. He tried the E.P.S. at 10 times the maximum allowed by the makers. He did not force the I.E.S. cells to their utmost maximum. He kept to the 10 per cent. for the potential, because he was accustomed to consider that the maximum at which the cells should be discharged. The report was dictated by him and type-written and then sent to Mr. Higgs. It was not prepared by him with a view to general publication He knew that Mr. Higgs was interested in the cell from the beginning.

By His LORDSHIP: He did not know that Mr. Higgs wanted the figures for the purpose of showing them. Mr. Higgs did not tell him that he was going to show them. At the time that Mr. Higgs asked him for the results he thought they were only for his own personal information. In addition to the figures which appeared in the report he had his own notes and own curves and own data he had kept for the purpose of preparing a report on the subject. He did not continue the tests beyond a certain time because the works were removed to Woking. When he first began the experiments he had meant to make very elaborate tests. He gave Mr. Higgs such results as he thought reliable up to that time. He had meant to test the resistance of the cell and make the report of scientific interest. He was not called upon by the defendants to show the results to them, and he received no communication from them to the effect that they were going to criticise the report, nor did they ask his permission to do so. He had no knowledge that Mr. Higgs had parted with it or shown it to anybody. He did not wish the report to be published as a scientific report. Mr. Higgs was familiar with the tests he had employed. He emphasised to Mr. Higgs that isolated tests were valueless. He explained to him that he had taken repeated charges and discharges. The size of the cell was absolutely immaterial. There was no ground for the suggestion that he had suppressed the fact that the cells had been damaged. The cells were not damaged. The experiments lasted altogether, continuously, for three months. He had absolutely no sort of interest in the success of the battery in question. It was untrue to say that his results were erroneous or reckless.

Cross-examined by Mr. Asquith, WITNESS said that his report was intended to convey an idea to commercial men of the value of the I.E.S.

Digitized by Google

cell. He thought Mr. Higgs wanted it for his own information, but if he had been asked whether it was likely that Mr. Higgs would show it to other people he should have said it was. It was always intended that the results of his experiments should be published, but witness did not ask for remuneration until the appearance of the article complained of as a libel. The report was intended as a report to Mr. Higgs, and not as a public report. The cells and materials used by him were placed at his disposal by the I.E.S. Company. Asked if it was in reference to the use of the battery for traction purposes that his experiments were conducted and his report made, witness said No, but it had a particular value for traction purposes. At the present moment the application of electricity for traction purposes was one of the most difficult and important matters for the consideration of electrical experts. E.P.S. cells had been used for traction purposes. The three things essential for traction purposes were high capacity, mechanical durability, and light weight. Upon every one of those points he said and thought the I.E.S. cell was the best now before the world. There were 11 cells in the battery, and three plates in each cell. He could not say whether there was such a thing known to the market as a cell of the E.P.S. type used for practical purposes containing as few as three plates. The E.P.S. cells had to have a great number of plates, because their capacity was low. The number of plates was a question of capacity. In connection with his experiments in this instance he did not test an E.P.S. cell, but he had tested E.P.S. cells over and over again, and his reference to the makers would, he thought, prevent a commercial man from drawing the inference that he had experimentally contrasted the results given by the E.P.S. and I.E.S. cells. He was aware that there were a great many types of E.P.S. cells, but he took the L type instead of the K type, because that was recommended by the E.P.S. Company, and his experience was that at a higher rate of discharge than 4 amperes there would be injury to the plate in the way of reduction in capacity. It might be that the E.P.S. cells were in practice discharged at five or six times their normal maximum capacity, but that was contrary to the directions of the makers. He selected the L type of the E.P.S. Company because what was wanted for traction purposes was a high rate of discharge and a high capacity; and at any rate of discharge, the L type had a higher capacity than the K. The E.P.S. Company themselves recommended the L plate where these things were wanted in combination. He did not think he ought to have stated in his report the type of E.P.S. cell he had selected. His experiments were carried out by his assistants, he himself going to the works four or five times. The measuring instruments were supplied by the I.E.S. Company. He had discharged E.P.S. cells at about five times the rate allowed by the makers, with the result that there was a remarkably low capacity, and the peroxide was loosened. He believed the plates of the I.E.S. cells were encased in celluloid for the purpose of giving mechanical support, but such encasing was unnecessary.

WITNESS then gave, categorically, reasons for the statements in his report, and said that he did not know of an I.E.S. battery ever being used for traction purposes. He did not report on the merit of such a battery for traction purposes in every respect. When a battery was used for locomotive purposes it was exposed to vibration and shocks which would not occur in a laboratory, and all these things involved irregularities in the rate of discharge, and very great mechanical strains. Under these circumstances the mechanical structure of batteries of this kind for traction purposes was very important. A cell which was constructed to a large extent of celluloid was mechanically stronger than one of lead, because in acid the lead underwent chemical changes. In reporting on the capacity he did not consider the durability of the plates. At that time he could not pass an opinion on the durability of the cells; durability would be shown by experience in working on prolonged experiments. In his report there was nothing to indicate that the E.P.S. batteries were in boxes lined with lead, which weighed nearly two tons, while the I.E.S. batteries were in light ebonite boxes. In his opinion ebonite boxes would stand the wear and tear of tram-car life.

In re-examination, WITNESS said he was not invited to report on the actual operation of these batteries in use for traction purposes, and was not concerned with whether they were practicable for the purpose or not. His report did not purport to record any tests of durability, and none would be efficient except tests of actual and lengthy use.

Prof. AYRTON, electrical engineer, and Past President of the Institution of Electrical Engineers, examined, said that he had had many years' practical experience in secondary cells. He had had his attention called to the report in question, which had been the subject of criticism in the defendants' paper. He should have thought that if Mr. Hall had imagined that his report was going to be published in a technical paper, he would have entered into more details. He (witness) understood Mr. Hall's report quite well. He had heard the descriptions which the plaintiff had given in evidence of the methods of comparison which he had adopted, and he (witness) considered them quite fair. From personal tests which he had made to satisfy himself, Mr. Hall's "results" were not "reckless" or "erroneous"; he should say that they were substantially correct.

By His LORDSHIP: He did not test the E.P.S. cells to see what rates they could discharge at without injury. He assumed that the list rate of the makers gave that information, otherwise there was no object in giving the list rates at all.

Cross-examined by Mr. Asquith: The list rate was the rate the makers guaranteed the cells to give if long life was desired. What a business man wanted to know was the relative value of the two types of plate, and therefore it did not matter so long as it was correct.

Mr. LIMBREY HIGGS, a solicitor, in giving evidence and corroborating the evidence of the plaintiff, said that he had a few type-written copies of the report in question made to send round to some of his friends, but he did not know how the defendants got possession of it. The defendants did not ask his permission to use it.

Cross-examined, the witness said that he supplied copies of the report to Mr. Mayne, of the firm of New and Mayne.

Mr. J. BIRNIE EVANS, an Associate of the Institution of Electrical Engineers, and carrying on business in Palace-chambers, Bridge-street, Westminster, examined, said that for five years he had made a special study of secondary electrical cells, and was familiar with the different types of cells in the market. His attention was called to the new I.E.S. cell, and he tested it for his own satisfaction. He conducted the tests independently of Mr. Hall and in the ordinary scientific way. The results he arrived at corresponded with those arrived at by Mr. Hall, but some of them were slightly better. Substantially the results of his experiments agreed with the plaintiff's; but where they differed the difference was in favour of the I.E.S. cell. He heard Prof. Ayrton's evidence, and agreed with it in the main.

Mr. Conradi, an electrical engineer, corroborated Prof. Ayrton's evidence.

Mr. Benn, an electrical engineer, having given evidence to the same effect, the plaintiff's case closed.

Mr. ASQUITH, in opening the case for the defendants, said that it had been almost impossible for his learned friends who represented the plaintiffs, or himself, in the conduct of the case, not to give it the appearance of a contest of rival claims between two competing batteries; because it was impossible to examine and cross-examine the witnesses who had been called without trenching at any rate on that question. That was not in any sense the issue which the jury had to try. The only question that they (the jury) had to consider was, first, whether the article in question conveyed the imputation which the plaintiff suggested it did, and secondly whether that article in its fair and natural sense went beyond the limits of fair criticism in a technical journal in a matter of technical interest. He (the learned counsel) should show that the matter was brought before the defendants in the most legitimate way. Mr. Higgs, as they now knew, had a number of copies made of the report, and distributed them amongst his friends in order to induce them to join the Company, and in particular gave a number of copies to the firm of New and Mayne, who were jointly interested with him in the venture, and were the makers, in fact, of the battery. It happened that a gentleman wishing to purchase some form of accumulator from New and Mayne, sent an agent of his to negotiate about it, whereupon Mr. Mayne, one of the partners, having a pile of Mr. Hall's type-written reports before him, handed one across to the gentleman—the agent who had nothing whatever to do with the *Electrical Review*. That document having been handed over to a customer in the ordinary way, that customer brought it to the paper and therefore the document was obtained in the most legitimate manner possible.

His learned friend had made another suggestion equally unfounded—namely that inasmuch as the E.P.S. Company was an advertiser in the *Electrical Review*, it was in some way to its interests—a damaging comparison having been made with this rival battery—to get rid of that comparison and to carry the war into the enemy's camp. That suggestion was made upon imperfect knowledge, because not only the E.P.S. Company, but the I.E.S. Company were advertisers in the columns of this paper. What the defendants did when Mr. Hall's report came into their possession was to send it to a gentleman who they believed to be thoroughly competent, who was undoubtedly a practical expert in matters of this kind, and who was entirely independent of the Companies in question, and lived in Bradford, for him to comment upon it. What appeared in the paper was written by Mr. Rankin Kennedy under these circumstances, he having no personal acquaintance with the plaintiff. What struck Mr. Kennedy—as it struck a great many other people—was, that this report, framed in the manner it was framed, and inducing its conclusions by the process of reasoning which appeared on the face of it, was a report upon which the commercial public for whom it was intended would think they could safely act. He should submit that the article did not and never was intended to convey any imputation upon the honesty or good faith of the plaintiff. As far as he knew the newspaper never had any ground for making any such suggestion, and did not make it upon a fair construction of the article. He thought they would come to the conclusion that what they did say was that there was not on the face of the document sufficient data to support the conclusions the plaintiffs sought to erect upon it. Being of that opinion, they thought it was right that the public should have pointed out clearly to them the respects in which the report was deficient. The report was a comparison between the I.E.S. battery and the E.P.S. battery for traction purposes. The E.P.S. battery had the advantage of having been used for traction purposes. The object of the article was to institute a comparison between the batteries for that use, and the points of comparison were (1) capacity, (2) mechanical structure, (3) duration of life, and (4) weight. Those were the points it was necessary to establish in favour of the I.E.S. battery if its superiority over the E.P.S. battery was to be held to be established.

Proceeding to deal with the alleged libel, the learned counsel said it was natural that a journalist dealing with this question should point out that the report was vitiated by no mention of the type of E.P.S. battery used, and contended that, though the I.E.S. battery had never been on a tramcar, it might have been exposed in the laboratory to longer and more continuous tests than it was. It was true the E.P.S. Company's catalogue warned users of their cells not to exceed the normal rate of discharges, but in connection with the L type they said that under certain conditions the rates of charge and discharge specified might be increased on reference to the advice of the Company, and he should show that E.P.S. cells of every type were almost every day discharged at four or five times the maximum listed rates without the least injury to the plates. He did not think the writer could be said to have gone beyond the limits of fair criticism when he said that the plaintiff's was a reckless comparison, and his evidence would show that the E.P.S. cells stand the comparison. The statement in the report that the plaintiff was unable to make a comparison of the capacity of the I.E.S. Company's cells with the E.P.S. cells at the same

Digitized by Google

rates of discharge, because the E.P.S. cell would not stand such heavy discharges, the learned counsel asked the jury to say was a sanguine and reckless statement with reference to a cell which had only been tested in the laboratory and had never been applied for the purposes of traction at all. Lastly, weight was most important. Surely it was not the act of a careful man to make this comparison without warning his readers that wooden boxes lined with lead were used by the E.P.S. Company, while the I.E.S. Company used ebonite boxes, which he thought was one of the flimsiest substances that could be used for this purpose. These were the matters which occurred to the writer of the article and the conductor of the journal to call for strong and severe comment. The report did not give the information it ought to have given, and it omitted to give data which was absolutely necessary to enable the readers to test the justice of the writer's conclusions. If that were so, his clients were strictly within limits, and it was their duty as journalists to do what they could to point out the defective reasoning of this report and to warn the public not upon such materials to put their money into such a concern as this. He should submit that in doing that they were acting in no improper way, and that they had not exceeded the limits—necessarily wide and elastic—of fair comment on a matter which concerned the public

Mr. L. EPSTEIN, an electrical engineer and the inventor of the Epstein cell, said he thought the listed rate of the E.P.S. cells was a practical result, and the report unfairly compared practical results in the case of the E.P.S. cells with theoretical results in the case of the I.E.S. cells. In practice durability of construction and mechanical strength were the first considerations in cells. E.P.S. cells could be discharged for a certain number of times without injury at rates up to three times the normal rate. Epstein cells might be discharged to zero without taking any harm within a reasonable time. The mention of the Waddell-Entz cells in the report was misleading, because that was a different type of battery. His experience of celluloid was that it was a most uncertain material, and his firm had discarded it. In his opinion it was premature to recommend such a plate to the public. To a certain extent, to discharge E.P.S. cells at a higher rate than that which appeared in the catalogue was taking a liberty with them, and he would not specially recommend it. He was clearly of opinion Mr. Hall was not justified in drawing the conclusions he did as to practical results for traction purposes from the results of his laboratory tests. There was nothing in the report which had reference to anything but laboratory tests. Witness admitted that he published a report by Prof. Ayrton on his cells, which related to laboratory tests, but said he did not go so far as to say that on account of these tests his batteries were the most valuable for traction purposes. He put his batteries in ebonite boxes, and they answered in the majority of cases.

Mr. FRANK KING, manager of the Electrical Power Storage Company, examined, said that he had had a long practical experience of electric storage cells, and had read the report which Mr. Hall made. In his opinion the value of a cell for mechanical purposes was its mechanical strength. He did not see that the report dealt with the mechanical strength of the cell. Assuming that four discharges of the cell were made it would not give the plaintiff any idea of its durability, at least 20 discharges would be necessary; for that. Discharging at high rates must produce high rates of temperature in the cell. In that particular plate an increase of temperature would soften the celluloid and render it useless in giving additional strength to the plate. It got no advantage, therefore, from the use of celluloid. He had had a very large and distressing experience in the use of celluloid in the cells. He had used a great number of tons of it. Celluloid had been discarded as giving an additional mechanical strength to those plates. In his opinion a report was not justified which recommended the plates for locomotion purposes which did not deal with the durability or strength of them. His chief criticism on the cell in question was its deficiency in mechanical strength.

Mr. R. E. B. CROMPTON said he had for 15 years considered the application of electricity for traction purposes. The most important point to be considered in judging of the capacity of a battery for traction purposes were, first, durability and mechanical strength; and second, high rate of discharge. If the first were sacrificed to the second, the batteries were of no use for traction purposes. He had read Mr. Hall's report, and he agreed with the evidence which had been given by Mr. King. With regard to the employment of celluloid in secondary batteries, he said that he had used it largely, and had been a great sufferer from its continuous failure after it had been exposed for a considerable time to the action of the battery. That celluloid was absolutely useless in a battery was well known to everybody. He had not analysed the particular celluloid in use in the I.E.S. battery. If it were generally known that celluloid was of no use in this connection, he should account for the I.E.S. Company using it by saying it was due to their ignorance. The action of the battery on the celluloid began about nine months from starting. The type of lead cell which he had used from the beginning was being taken up by the largest users of accumulators. Assuming the durability of two cells were equal, the fact that one cell could be worked in practice at high rates of discharge would constitute an exceedingly valuable cell for traction purposes. If you were comparing two cells with equal durability, the usefulness would vary with the capacity for high rates of discharge.

Mr. T. E. GATEHOUSE, one of the editors of the *Electrical Review* said that Mr. Hall's report was sent to his newspaper in the ordinary way. It was brought by Mr. Schanschieff, an electrical engineer, who informed him he brought it from Mr. Ward, another electrical engineer. He read the report and sent it to Mr. Kennedy, a contributor to his paper, whom he knew as a thoroughly competent electrician. He had no interest in the I.E.S. or E.P.S. cells on any other electrical firm.

The LORD CHIEF JUSTICE: You thought it was a matter of interest in the particular line of industry with which you deal?—Of very great interest.

If these results were reliable it would show there were considerable advantages in this arrangement?—Yes.

He saw Mr. Kennedy's review before it was published, and inserted it after he had read it. He decidedly agreed with the criticisms Mr. Kennedy passed upon it. Witness produced a diagram showing how irregular was the rate of discharge of a battery during a 19min. run on a tramcar. He knew Mr. Hall by name, but he did not know that he was an associate of the same Institution as himself, though Mr. Hall described himself as such and gave his address. The report purported to be furnished to a private gentleman, but as it was not marked "private and confidential" he assumed it was a public document. He was afterwards informed by Mr. Higgs that it was a private document, but he thought it was all the more justifiable to criticise it because Mr. Higgs stated it was a report for commercial men. In his opinion the vital point was that Mr. Hall made no experiments on the life of the cell. There was nothing in the report to show that the I.E.S. battery was fit for traction purposes at all. With regard to the suggestion that the alleged libel charged Mr. Hall with foisting a worthless thing on the public, witness said a consulting engineer did not do that, though his report might be used for that purpose. Mr. Higgs' letter was published by him after the issue of the writ. Mr. Hall did not represent, nor did his solicitor represent, that this report was a private document.

Mr. ARTHUR SHIPPEY said that he was employed by Mr. Ward to obtain a light accumulator for him, and in consequence he called upon Messrs. New and Mayne. He saw Mr. Mann, the manager, who referred to the report of Mr. Hall, and witness was offered a commission to sell I.E.S. batteries.

Mr. LAWSON WALTON said that Messrs. New and Mayne were making for the I.E.S. Company, and Mr. Higgs sent them 15 or 20 copies of Mr. Hall's report.

WITNESS said Mr. New gave him a copy of the report in order that he might use it for obtaining orders. He took the report to Mr. Ward, who, being a practical man, asked him for curves.

Mr. RANKIN KENNEDY said that he had had 18 years' experience in electrical matters, and was a pupil of Lord Kelvin. He had been a contributor to the *Electrical Review* on technical matters, and wrote the article in question. He did not know Mr. Hall, and had no interest in the I.E.S. or E.P.S. cells. The report was sent to him, without any communication, to treat as he thought proper. He commented on the report, not on the engineer or the batteries. He treated the report as a public document. He had never seen an I.E.S. battery, but he had seen one which was equivalent. Asked what was his ground for saying that the figures in the report were transparently erroneous, witness said that any engineer would know that 5 H.P. batteries would be useless for traction purposes, because three times the normal horse power of the batteries had to be provided for. The statement that the I.E.S. cell could be discharged to a lower capacity than any other cell was erroneous, because he knew many cells which could be discharged to zero without injuring them. The main error in the report was that there were no details given. If he had been informed that Mr. Hall had furnished Mr. Higgs with details, that would very much have modified his opinion. There was nothing in the report to support the statement that the I.E.S. battery was the best for traction purposes.

This concluded the evidence.

Mr. ASQUITH, in summing up the case for the defence, said the question, and the only question, was whether this report, understood in the sense which an ordinary reader of average intelligence would put upon it, did contain imputations upon the character and competency of the plaintiff, which were in excess of fair journalistic criticism. His learned friend opened the case as a case in which a newspaper had, by illegitimate means, got possession of a private document and had utilised its columns, not for the purpose of fairly criticising the information it contained, but for the purpose of puffing the products of a rival company, which was a large and lucrative advertiser in its columns. The facts made it abundantly that this was nothing of the kind.

Mr. LAWSON WALTON having replied,

His LORDSHIP, in summing up, said that there was no class of cases in which the functions of the judge were so limited, and the functions of the jury so wide, as in actions of that kind. The first point was whether the plaintiff's report was or was not a fitting subject for criticism. The plaintiff, by his counsel, said it was not, and that it was a private document; also he alleged that it was a matter which did not concern the public, and with which a public journal dealing with those subjects had no legitimate concern. He (his Lordship) had no doubt in his own mind that the plaintiff must have known, as a man of common sense and experience, that Mr. Higgs was not paying for the report in order to put it in the waste paper basket or lock it up in a drawer. His Lordship then referred in detail to the evidence, which showed how the report came to the defendants' hands, and was handed by Mr. Gatehouse, the editor, to Mr. Kennedy for criticism. If the matter was one for legitimate criticism, as he (his Lordship) thought it was, having regard to the fact that the question of storage batteries was of great importance in the electrical world, the jury had then to consider whether the defendants had gone beyond the bounds of fair criticism. To his mind the most important part of the article complained of was that in which reference was made to attempts by so-called expert reports to foist upon the public a certain manufacture, and it was for the jury to say whether that meant that the plaintiff lent himself to an attempt to foist on the public a worthless invention. There was no evidence for saying that such an imputation could be sustained, and it was without justification; in fact, the learned counsel for the defendants had disclaimed that there was any intention of making it. The question, however, was not the meaning of the writer, but what the words meant to ordinarily reasonable men.

The Jury, after a short deliberation, returned a verdict for the plaintiff for £100 damages.

Judgment accordingly

Digitized by Google

Digby v. Wyatt.

This case came before Mr. Justice Grantham on Friday last, brought by Mr. T. J. Digby, electrician, against Mr. Frank Wyatt and his wife, proprietors of the Duke of York's Theatre, London, to recover damages for the detention of certain electrical appliances.

The plaintiff's case was that under an agreement with Mr. Horace Sedger, lessee of the theatre, he supplied the electric light appliances for the stage during the performances of "Baron Golosh," the piece being produced under an agreement by which the expenses were to be borne by Mr. Sedger and the defendants. The plaintiff said Mr. Sedger thought that he had been released from liability under his arrangement with the plaintiff by the agreement with the defendants, and as he (the plaintiff) had failed to come to any arrangement with the defendants with regard to the lighting of the theatre by electricity, he applied to Mr. Sedger for permission to remove his appliances. The defendants, however, refused to allow the removal to be effected, and the result was that when he was asked to supply the necessary electrical apparatus for the staging of "The Artists' Model," at another theatre (the Lyric), he was compelled to make new arc lamps at a cost of £63.

The defence was that the plaintiff was not entitled, at any time before May 25th, to any of the plant in question. Moreover, the defendants further pleaded that when the plaintiff produced Mr. Sedger's authority to remove the plant they permitted him to do so.

In the result His Lordship gave judgment for the plaintiff for £10, with costs on the higher scale.

Fareham Electric Light Company (Limited) v. Fareham Urban District Council.

In the Queen's Bench Division on Wednesday, before the Lord Chief Justice, Mr. Channell, Q.C., who appeared for the Fareham District Council, said: Your Lordship will remember that in this case, which was tried last sittings, my learned friend, Mr. Robson, appeared for the plaintiffs. Your Lordship recollects that the question in the case was as to whether or not the contract should be carried out. What the local Council did afterwards was this. They thought the best thing they could do would be to go to the ratepayers again and ascertain their opinion as to the course that should be adopted, that is, whether they would carry out the contract or pay the damages. The Council accordingly took a poll of the ratepayers, with the result that there was a small majority in favour of carrying out the contract instead of paying the domages. Some time was of course wasted over these proceedings, and then my clients got into communication with the Lighting Company again, when it turned out that there was a little misunderstanding as to what the offer was. There were apparently two points of difference. In the first place the Urban District Board thought that the offer was to the effect that proposal that they should carry out the original contract was conditional upon their getting the sanction of the Local Government Board to the proposed loan. My friend's clients, however, said they never intended anything of the sort, their offer being that we should either purchase the works or pay the damages. That is the first point of difference. The next point is as to the payment of interest. The plaintiffs say that if the contract is carried out they ought to have interest from some antecedent date upon the purchase money. On this point there had been some dispute, and about a fortnight ago I was consulted by my clients about these disputed points, and I suggested that the first thing to do was to go to the Local Government Board and see what they could do about getting the sanction of that Board to a loan; they would then know whether a loan could be obtained or not. My clients acted upon that advice, but at present they have not received any definite answer. I understand, however, that they have received a letter from the Local Government Board this morning, in which it is stated that the Board are prepared to sanction a loan for part of the amount, but that the other part of the loan asked for requires further consideration. Under these circumstances, I suggest that we should be granted a little more time to consider our position.

Stay of execution for fourteen days granted.

Fraser v. South.

This case was heard yesterday (Thursday) in the Westminster (London) County Court, and was a claim for £13 for two arc lamps supplied to the defendant, Mr. Harry South, electrical engineer, of Garrick-street, W. The defendant was stated to have sent in November last two arc lamps on approval, and a month was allowed in which to try them. The lamps were not returned. The defence was that plaintiff's late partner offered to lend the lamps to one of defendant's customers on approval, and that defendant merely acted as the agent of the manager of the music hall at which the lamps were to be tried.

Judgment was given for the amount claimed with costs, the judge (Mr. Lumley Smith) holding that the defendant had kept the lamps too long.

Long-Distance Telephone in Russia.—According to reports received, the Russian Government has resolved to erect a telephone line between St. Petersburg and Moscow. The line will consist of four copper wires, and as all preliminary work has already been done, the completion of the line is expected by May 1, 1896. The line will at first be used exclusively by the Government.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK will be ready in a few days, Subscription Orders (5s. 9d. post free, abroad 6s. 6d.) must be sent in by Wednesday next. After that date the published price of the Directory and Handbook will be (as usual) 7s. 6d., post free 8s. 3d., abroad 9s.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

TENDERS INVITED.—The Vestry of St. John, Hampstead, require tenders for works and materials for one or three years for (1) coals and coke, (2) oils for machinery at electric lighting station, (3) tools, implements and other electrical engineers' stores, (4) carbons, lamps and other stores for electric lighting station, (5) removing ashes from electric lighting station. Some further particulars are given in our advertisement columns. Tenders must be sent in to Mr. Arthur P. Johnson, Vestry Clerk, by 4 p.m. of February 12th.

——— The Corporation of Huddersfield invite tenders for two steam boilers, four mechanical stokers and one surface condenser with air and circulating pumps. Specifications, &c., may be obtained of Mr. A. B. Mountain, Borough Electrical Engineer, St. Andrews-road, Huddersfield, and tenders must be sent in to Mr. F. C. Lloyd, Town Clerk, Town Hall, Huddersfield, by Tuesday, February 4th.

——— The Great Indian Peninsular Railway Company invite tenders for the supply of stores, including telegraph materials, iron telegraph wire, &c. Tenders to the Secretary, 43, Copthall-avenue, London, E.C.

——— Tenders are invited for the concession for the electric lighting of Sainte Croix de Teneriffe, Canary Islands, for 35 years. Tenders to the Ministère de la Gobernacion, Madrid, by Feb. 29th.

LIGHTING SCHEMES INVITED.—It will be seen by our advertisement columns that the Urban District Council of Eston, Middlesboro', invite schemes for lighting the district by electricity. A plan of the district can be seen and particulars obtained on application to Mr. F. W. Stainthorpe, A.M.I.C.E., District Surveyor, Grangetown, Yorkshire, to whom schemes must be sent in not later than May 1st next. Mr. Jno. T. Belk is clerk to the Council.

TENDERS ACCEPTED.—Messrs. Siemens Bros. and Co. (Limited) have received an order from the Gas and Electricity Committee of the Edinburgh Corporation for the supply of additional engines and dynamos for their electric lighting station. The contract for the supply of boilers has been awarded to Mr. Sinclair.

Digitized by Google

SALE BY TENDER.—Messrs. Wheatley Kirk, Price and Goulty announce the sale by private tender (by direction of the Court) of a portion of the plant and machinery, the whole of the utensils, office furniture, stock and stores, &c., on the premises known as the Smithfield Works, New Road, Blackwall, London, E., formerly occupied by Messrs. D. W. Forbes and Co. (Limited). In our advertisement columns some further particulars will be found. Tenders should be sent by post to Mr. W. C. Hewlett, chief clerk, at the Chambers of Mr. Justice Kekewich, Royal Courts of Justice, Strand, London, by Wednesday, February 5th. Particulars and conditions of sale, forms of tender, orders to view, &c., can be obtained of the firms mentioned in the advertisement.

SALE BY AUCTION.—Messrs. Hepper and Sons have received instructions from the Corporate Property Committee of the Leeds City Council to sell by auction at the Municipal Buildings, Leeds, on Thursday, February 13th, at two o'clock, a large quantity of electric lighting plant, including engines by Willans and Robinson and Crossley, boilers by McLaren, dynamos by Mather and Platt and Paterson and Cooper, E.P.S. accumulators, and a quantity of apparatus and instruments, forming the complete installation which was some time ago erected at the Municipal Buildings, and which is now dispensed with as current is taken from the local Electric Supply Company's mains. Some further particulars are given in our advertisement columns. Catalogues are now ready, and may be obtained of the auctioneers, East-parade, Leeds.

REMOVAL.—The National Telephone Company (Limited), notifies that the "Sale Outright of Instruments and Lines Department" has been removed from Falcon-avenue, Aldersgate-street, to the City District Offices, London Wall, E.C.

BUSINESS CHANGES.—Messrs. Swinburne and Co. (Limited) inform us that arrangements have been made to amalgamate their business with that of the Nalder and Harrison Construction Syndicate (Limited), the new firm's title being "Nalder and Harrison (Limited) and Swinburne and Co. (Limited)," the works of the combined firm being situate at Bow Common-lane, London, E Mr. Holt, late General Manager of Swinburne and Co., joins the Board of the amalgamated companies.

APPOINTMENT VACANT.—The Electric Lighting Committee of the Edinburgh Town Council, at their meeting on Wednesday, resolved to advertise for a resident electrical engineer in succession to Mr. E. W. Monkhouse, at a commencing salary of £400 per annum.

LIQUIDATIONS.—We have received a letter from Mr. Sydney F. Isitt, Liquidator in J. C. Howell (Limited) (in liquidation), calling a meeting of creditors, to be held at 6, Old Jewry, London, E.C., on Wednesday next at 12 o'clock, when Mr. Isitt proposes to report on the progress of the winding-up. The circular states that the Liquidator has been informed by Mr. Howell that some of the creditors have been paid. In the event of its becoming possible by Monday next to continue the payment of the liabilities as they become due, in accordance with the terms of the original arrangement, creditors will be advised, and in that case no meeting will be held.

——— By an order of the Sheriff's substitute of the county of Renfrew, J. W. Weens and Alexander Wylie, engineers, &c., of Johnstone, Scotland, notify that they have presented a petition to be finally discharged of all debts contracted by them before the date of the sequestration of their estates.

——— At a meeting of the proprietors of the Merveilleuse Electric Arc Lamp Syndicate (Limited), on December 31st, it was decided to wind up the Company voluntarily. This resolution was confirmed on January 16th, and Mr. A. Conder, accountant, was appointed liquidator.

——— A meeting is to be held at the offices of Messrs. Owston, Dickinson and Simpson, solicitors, 23, Friar-lane, Leicester, on February 26th, at 3 p.m., to receive an account of the winding-up of the English Electric Manufacturing Company (Limited).

BERLIN INDUSTRIAL EXHIBITION, 1896.—Some concern is evidently felt by the organisers of this exhibition at the tension existing between England and Germany at this moment. In a letter just to hand Englishmen are asked not to allow "the unfortunate irritation recently prevailing in both countries" to in any way mar the success of the forthcoming exhibition, with which considerable progress has been made.

CATALOGUE.—We have received a copy of Messrs. Easton, Anderson and Goolden's (Limited) latest catalogue of electric, steam, hydraulic and general engineering machinery. The work is divided into sections, each copiously illustrating one department of work undertaken by this firm. The first section is on "Waterworks," a branch of engineering equipment in which this firm has done some first-class work at home and abroad. Particulars of various forms of electrically-driven pumps are included in this section. The second section deals with "Pneumatic Machinery," and the third with miscellaneous plant. We notice some good illustrations of the Grafton high-speed enclosed steam engine, and particulars of this serviceable motor. Following these is a section on "Boilers," a class of work for which Messrs. Easton, Anderson and Goolden (Limited) have made a good reputation, both in and out of electric supply stations. Hydraulic and electric lifts, cranes, travellers, &c., occupy considerable space towards the end of the book; and later still comes a section specially devoted to "Electrical Machinery," in which all classes of lighting, mining, coal-cutting, signalling and traction plant, driven by electricity, are included. The catalogue is strongly bound in cloth boards, and both in the style of its get-up and in the character of its contents is a credit to a firm of high standing.

PRICE LIST.—Messrs. Beanland, Perkin and Co., of Leeds, forward a price list of "B. P. C." dynamos and motors.

ABERDEEN.—The Electric Lighting Committee have just presented their accounts for the year ended December 31st. The revenue for this period amounted to £3,611. 8s. 9d., and the expenditure was £1,356. 18s., or a balance of £2,254. 10s. 9d. The sum of £1,819. 10s. has been set aside for interest and depreciation, leaving a clear net profit of £435. 0s. 9d. The Corporation has had authority to borrow £32,000, and has already exercised its power in respect to £29,800 of this sum. It is understood that the Committee will shortly recommend considerable extensions of the present electric lighting area, and it is also probable that they will reduce the price of current from 6d. to 5d. per unit.——At the last meeting of the Docks and Pilotage Committee of the Harbour Board the question of lighting the quays by electricity was under consideration, and the matter was referred to a Committee, consisting of Messrs. Murray, Sangster, Connon and Meff, who are to act with the engineer in collecting information as to cost, &c. The Committee are to consider and report upon the question whether it would be cheaper to take current from the Corporation mains or to put down an independent generating plant.

BIRMINGHAM.—In reference to the application of the Birmingham Central Tramways Company for permission to introduce the overhead electric traction system on their Nechells route, the Public Works Committee of the Corporation have just decided to recommend that permission be given to the Company to employ this system on the tramways between Albert and Nechells Park-roads (a distance of about 2¼ miles) for a period of six months, subject to the approval of the Board of Trade, and also to such conditions as the Board and the Committee may think fit to impose. Should the Corporation decide not to grant a renewal of the consent the Company are to remove the posts and wires and reinstate the roads and footpaths at their own cost. It is stated that the Directors of the Company have agreed to these conditions.

BRECHIN.—Owing to the inferior quality and the high price of the gas supplied by the local gas company, many of the principal shops and business establishments in this town have already put down independent electric lighting plants. The Brechin Paper Mill has adopted this course. Current is supplied by a Mather and Platt dynamo, driven by a Shanks engine. About 110 incandescents are used.

BRADFORD.—The Gas and Electricity Supply Committee have appointed Mr. Thomas Barker, architect, to draw up plans for the proposed extension of the Corporation electricity works.

BURSLEM.—Messrs. Crompton and Co. have recently fitted for the electric light the extensive baths erected by the Corporation of Burslem. The erection and fitting of the baths has cost £10,500. Messrs. Crompton's representative at Burslem for this work was Mr. G. Heath.

CHELMSFORD.—Messrs. Crompton and Co. have written to the Town Council offering to dispose of the undertaking of the Chelmsford Electric Lighting Company to the Council, one inducement held out being that the additional capital thereby accruing to Messrs. Crompton and Co. would be used in the extension of the works now in process of erection, in this way contributing to the increased prosperity of the town. Messrs. Crompton's letter states that it is now an accepted principle that Corporations should have the public lighting arrangements under their own control, and that the present is a fitting opportunity to consider this important question. The terms of purchase were not mentioned in the letter, and some discussion arose as to whether, before referring Messrs. Crompton's communication to a Committee for consideration, the terms upon which the purchase could be effected should not be given. It was finally decided that the Committee should confer with Messrs. Crompton and Co. as to the terms of their offer, and then consider the proposal generally.——It is stated that Messrs. Crompton and Co. have in contemplation the aquisition of a new site for their works near the railway.

EDINBURGH.—For some time on Wednesday the Electric Lighting Committee of the Corporation discussed the subject of the contemplated extension of the electric lighting area, and finally authority was given for the acceptance of offers for boilers, super-heaters, mechanical stokers, dynamos, and other plant, estimated to cost over £20,000. It was also decided to recom-

Digitized by Google

mend that opposition be offered to the petition presented by Dr. J. Hopkinson and the Westinghouse Company to the Privy Council, praying for an extension of time for their patents in connection with the three-wire system.

ELECTRIC TRAMWAYS.—An interesting series of articles on the present and prospective developments of electric tramways is appearing in the *Belfast News Letter*.

FENTON.—The District Council at their last meeting instructed the Clerk to act in conjunction with the local authorities of Stoke, Burslem and Tunstall, in making objection to the application of the promoters of the Provisional Order for the construction of electric tramways in the district.

GLASGOW.—The Committee of the Police Department have appointed a sub-committee, consisting of Messrs. Primrose, Guthrie and Cleland to visit Edinburgh and inspect and report upon the system of electric lighting in that city.——It is stated that the Glasgow office of the Silver-town Company have secured the contract for a complete installation of electrical machinery for the Glasgow Subway Company (Limited), including engines and dynamos, electrically-driven pumps, the lighting of 15 stations and trains, and the supply of electric power for elevators, &c.

HACKNEY (LONDON).—At their meeting on Tuesday last the Vestry decided to adopt the combined electric lighting and refuse destructor scheme, particulars of which were given in our issue for December 13th. The scheme is estimated to entail an outlay of about £80,000.

HASTINGS.—Mr. F. Bruce, of Hastings, has been entrusted with a contract for the wiring of the new wing of the Victoria Hotel, St. Leonards. The convent at Church-road is also being fitted up for the electric light by Mr. Bruce.

ISLINGTON (LONDON).—Current for private lighting lighting will be available from to-day. The street lighting, however, will not be started until March, after the formal opening by the Lord Mayor.

KINGSTON-ON-THAMES.—At the last meeting of the Town Council a letter was read from the Surveyor to the Hampton Wick District Council stating that he had no instructions from his Council with respect to the proposal to extend the electric light mains to Hampton Wick, but he offered no objection to a circular being sent by the Corporation to the inhabitants of the district for the purpose of ascertaining the quantity of current that would be required. The Town Clerk recently wrote to the Surbiton District Council suggesting that it should re-consider the question of entering into an arrangement with the Corporation for the supply of electric current, but the Surbiton Council has just replied stating that they had appointed a consulting electrical engineer, and that electric lighting tenders were under consideration.

LEEDS.—At last week's meeting of the Highways Committee of the Corporation, Dr. J. Hopkinson's recommendations with regard to the electrical equipment of the Leeds tramways was approved. The scheme is for the construction of an electrical tramway from Kirkstall to Roundhay, with the Westinghouse closed conduit system in Boar-lane. The following is Dr. Hopkinson's estimate for the rolling stock, plant and apparatus required in the installation :—

Trolley wire erected with insulators, 14 miles at £190 ..	£2,660	0	0
Poles for two trolleys, seven miles at £1,196 per mile ..	8,372	0	0
Bonding rails, at £150 per mile of single track	2,100	0	0
Seven miles of 0·15 square inch cable, at £317 per mile	2,219	0	0
Closed conduit for 310 yards of double rail, at £1. 12s. 6d. per switch.....	251	17	6
20 cars at £750	15,000	0	0
Two boilers, each 200 H.P., with steam pipes and economisers, at £700	1,400	0	0
Two condensing engines, at £1,400	2,800	0	0
Two dynamos, at £600	1,600	0	0
Switchboards and instruments.....	740	0	0
Two batteries, at £500.....	1,000	0	0
Instruments and switches, at £70 each station	140	0	0
Total	£37,882	17	6

LLANDRINDOD WELLS.—The Urban District Council has just decided to accept the proposal to light the public streets with incandescent electric lamps at an annual charge of 58s. 6d. per lamp per annum. There is to be a minimum of 70 lamps, each of 32 c.p., and the agreement is to continue in force for seven years. The maximum charge for current of 8d. per unit is to be reduced to 7d. when the equivalent of 3,000 16 c.p. lamps are installed.
